Inria Rennes-Bretagne Atlantique

Rennes, Nov. 2017 – Jan. 2018

outline

introduction

definition and properties

variants and their derivatives

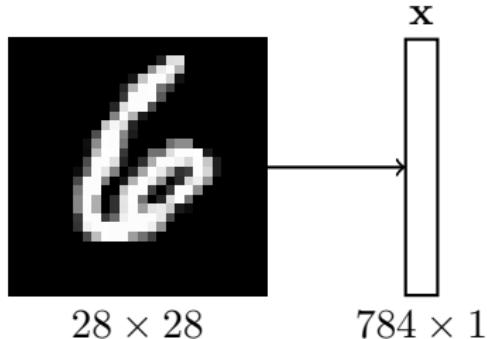

pooling

fun

network architectures

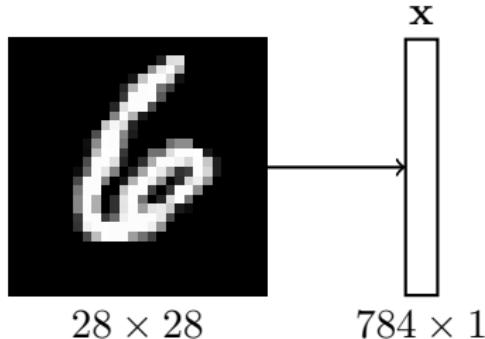

introduction

input image representation

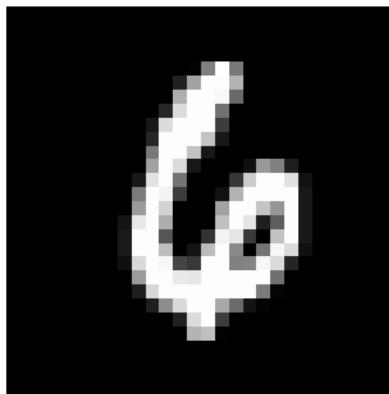

- the two-layer network we have learned on MNIST can easily classify digits with less than 3% error, but **learns more** than actually required
- remember that for both MNIST and CIFAR10, we flattened images (1-channel or 3-channel) into vectors, and the **order** of the elements (pixels) plays no role in learning
- so what if we **permute** the elements in all images, both training and test set?

input image representation

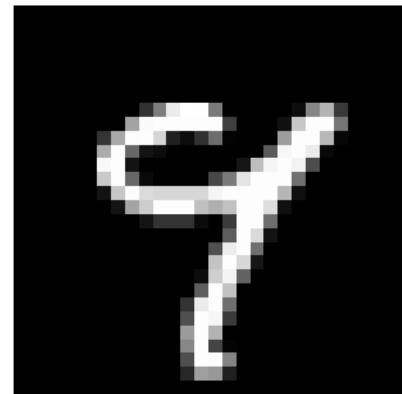

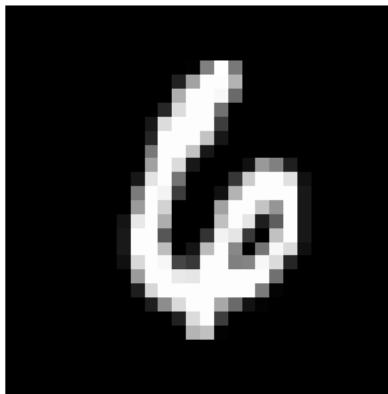

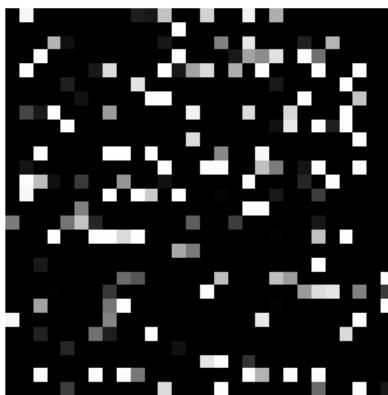

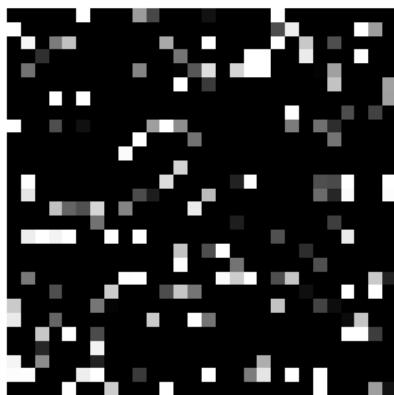

- the two-layer network we have learned on MNIST can easily classify digits with less than 3% error, but **learns more** than actually required
- remember that for both MNIST and CIFAR10, we flattened images (1-channel or 3-channel) into vectors, and the **order** of the elements (pixels) plays no role in learning
- so what if we **permute** the elements in all images, both training and test set?

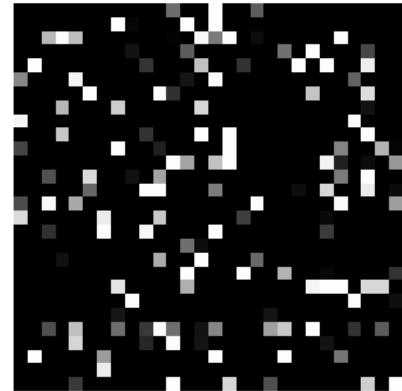

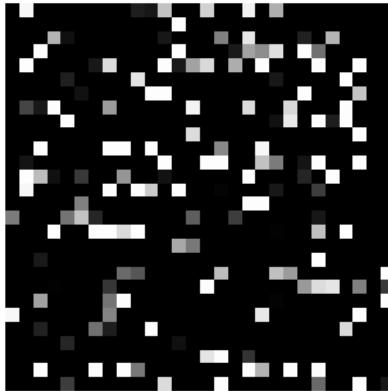

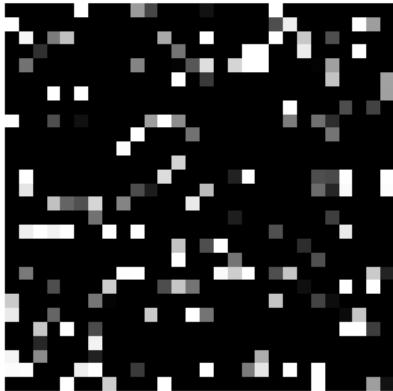

shuffling the dimensions

shuffling the dimensions

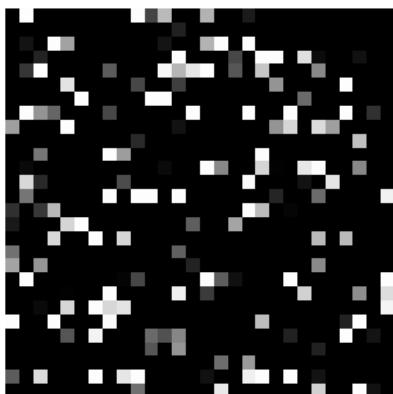

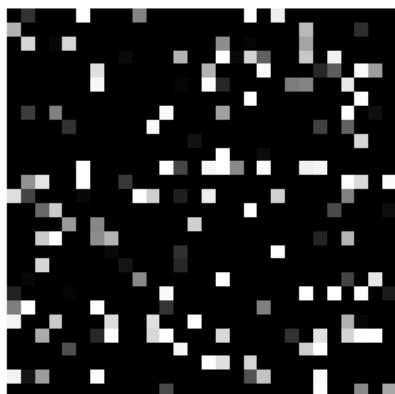

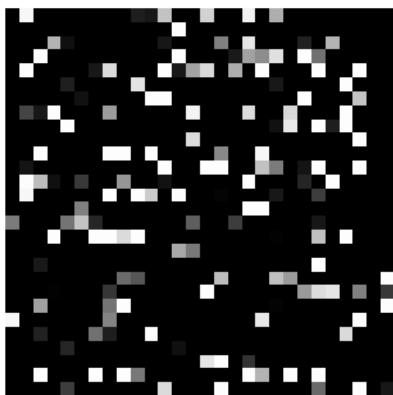

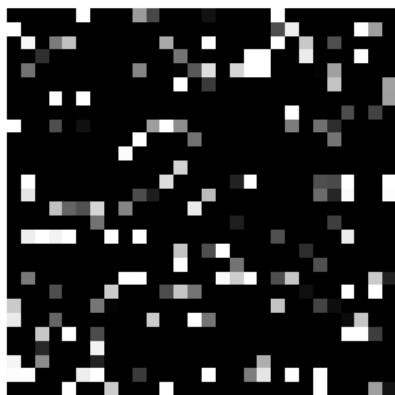

shuffling the dimensions

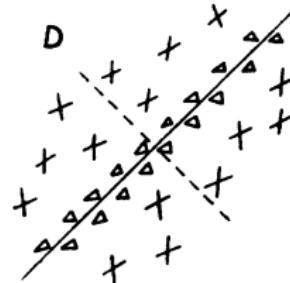

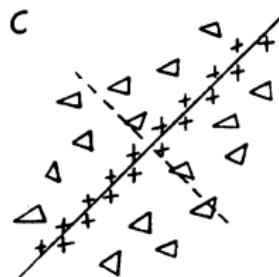

- this is what the computer sees
- it must make more sense when you start looking at more than one samples per class

shuffling the dimensions

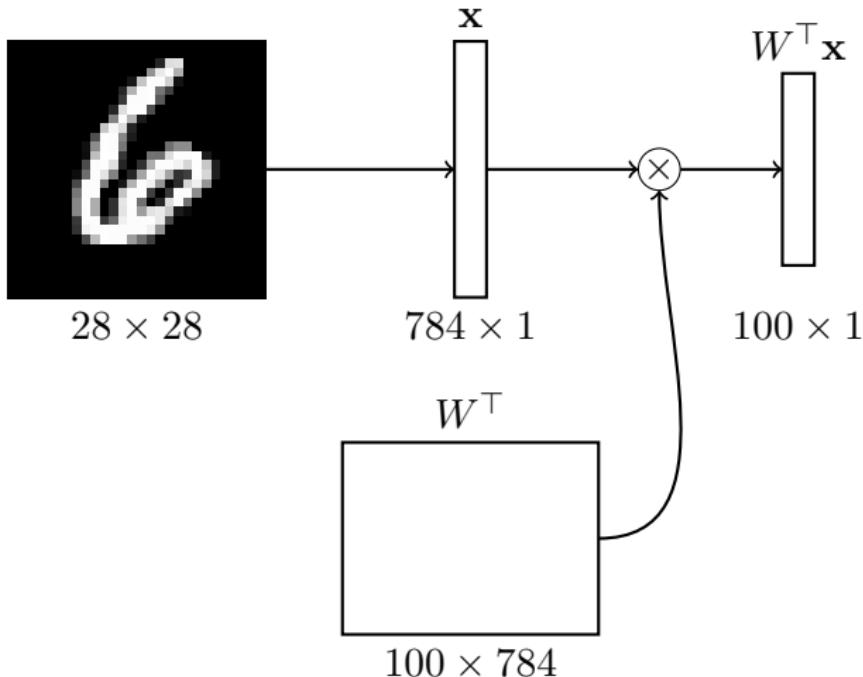

remember receptive fields?

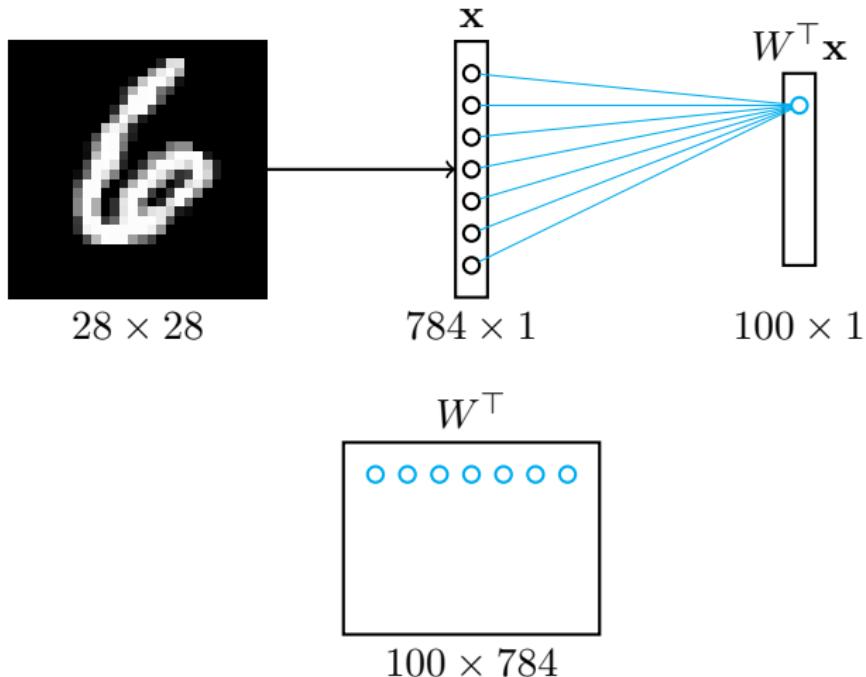

- A: 'on'-center LGN; B: 'off'-center LGN; C, D: simple cortical
- each cell only has a localized response over a **receptive field**
- **x**: excitatory ('on'), **△**: inhibitory ('off') responses
- **topographic mapping**: there is one cell with the same response pattern centered at each position

matrix multiplication

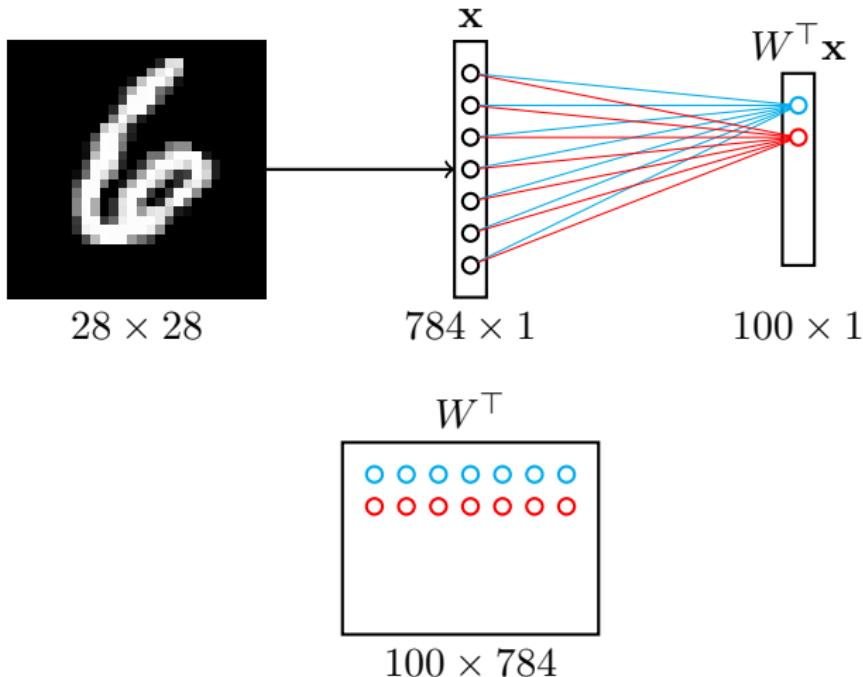

- inputs \mathbf{x} are mapped to activations $W^\top \mathbf{x}$
- columns/rows of W^\top correspond to input/activation elements

matrix multiplication → fully connected

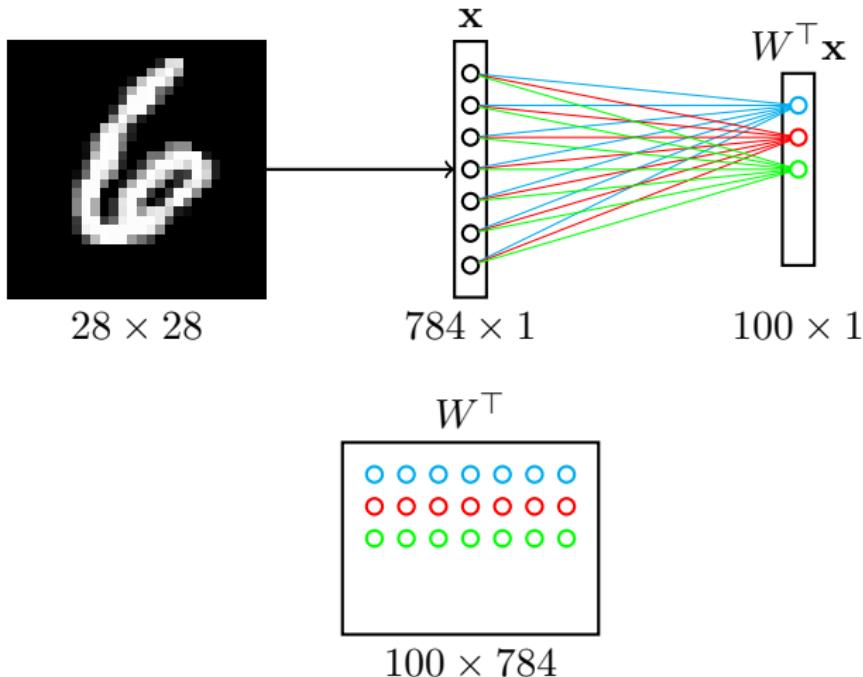

- each row of W^T yields one activation element (**cell**)
- each cell is **fully connected** to all input elements

matrix multiplication → fully connected

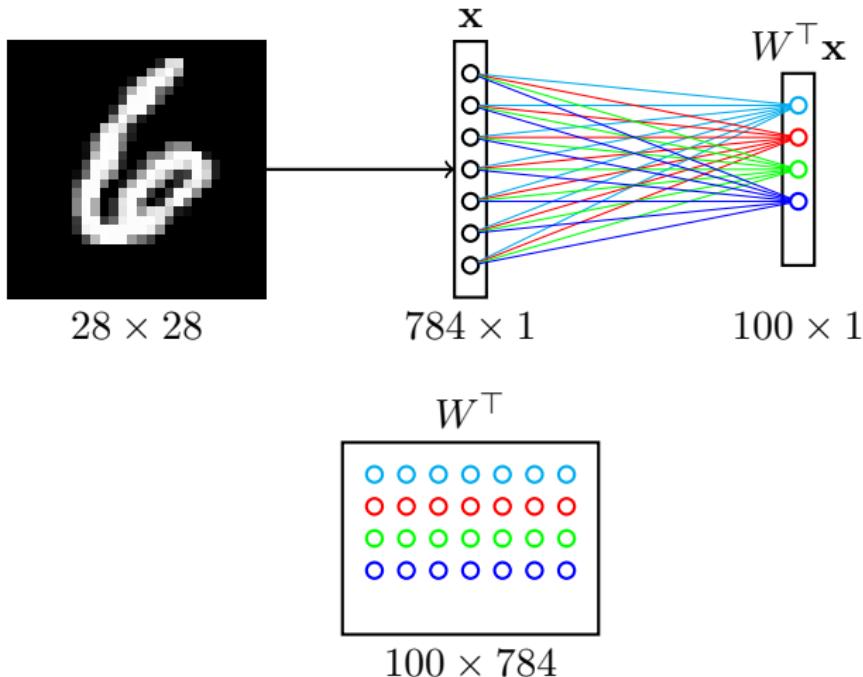

- each row of W^T yields one activation element (**cell**)
- each cell is **fully connected** to all input elements

matrix multiplication → fully connected

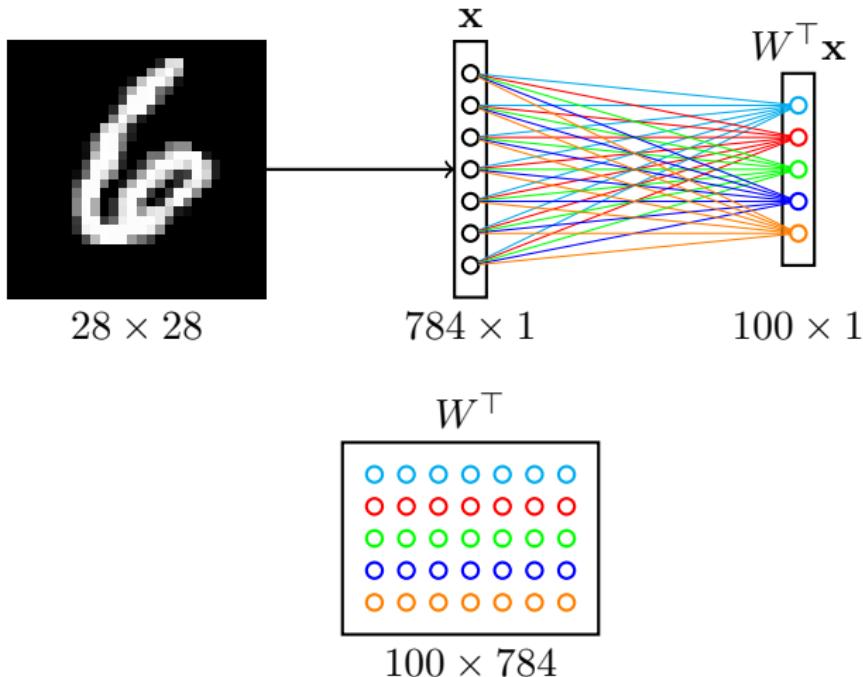

- each row of W^T yields one activation element (**cell**)
- each cell is **fully connected** to all input elements

matrix multiplication → fully connected

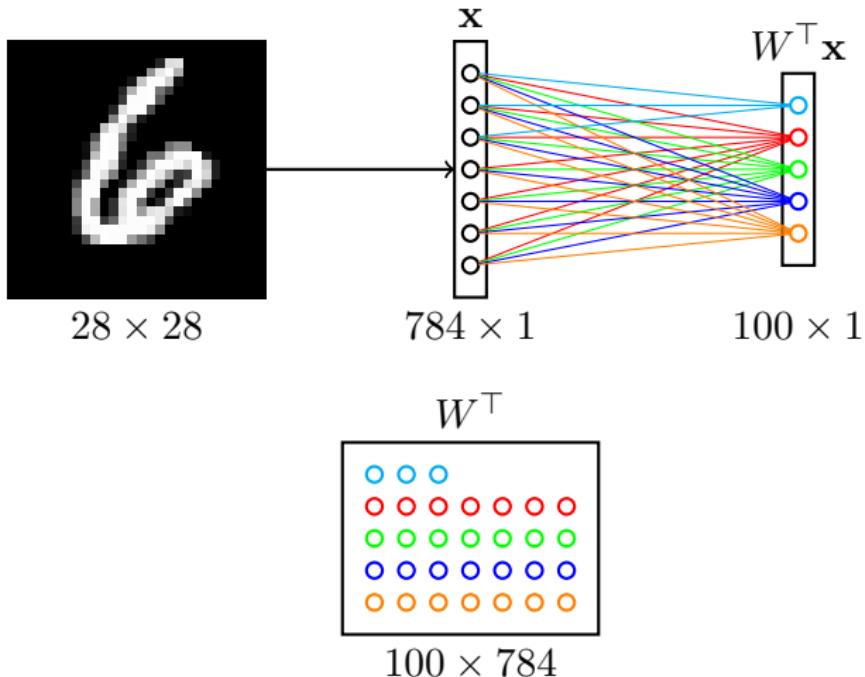

- each row of W^\top yields one activation element (**cell**)
- each cell is **fully connected** to all input elements

matrix multiplication → fully connected

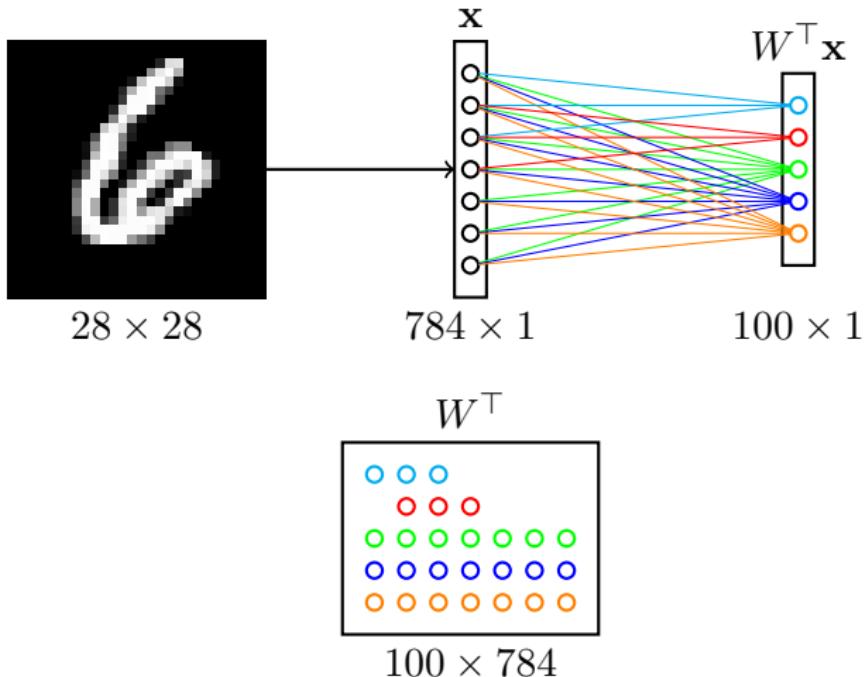

- each row of W^\top yields one activation element (**cell**)
- each cell is **fully connected** to all input elements

sparse connections

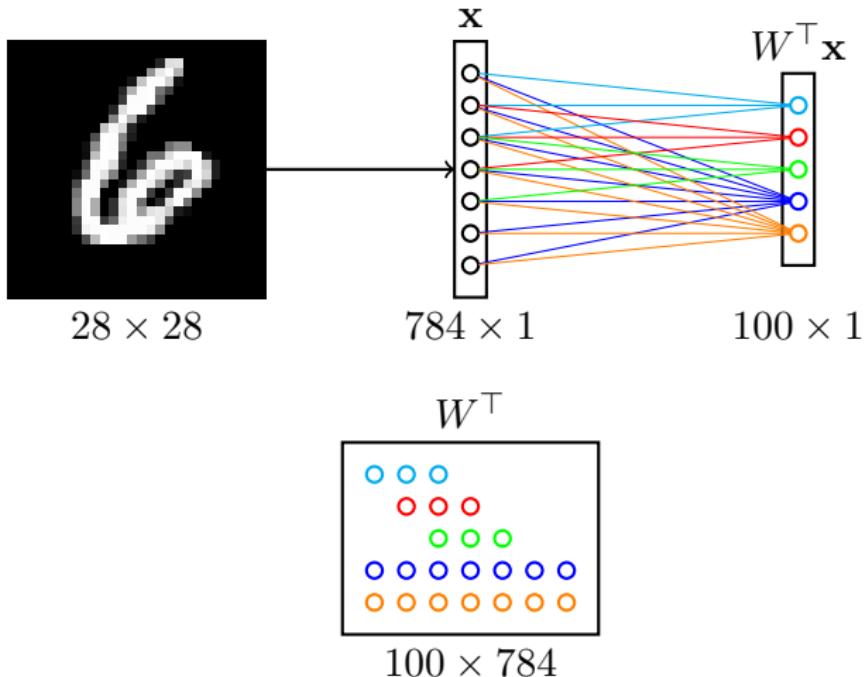

- now, we only keep a **sparse** set of connections
- and matrix W becomes sparse as well

sparse connections

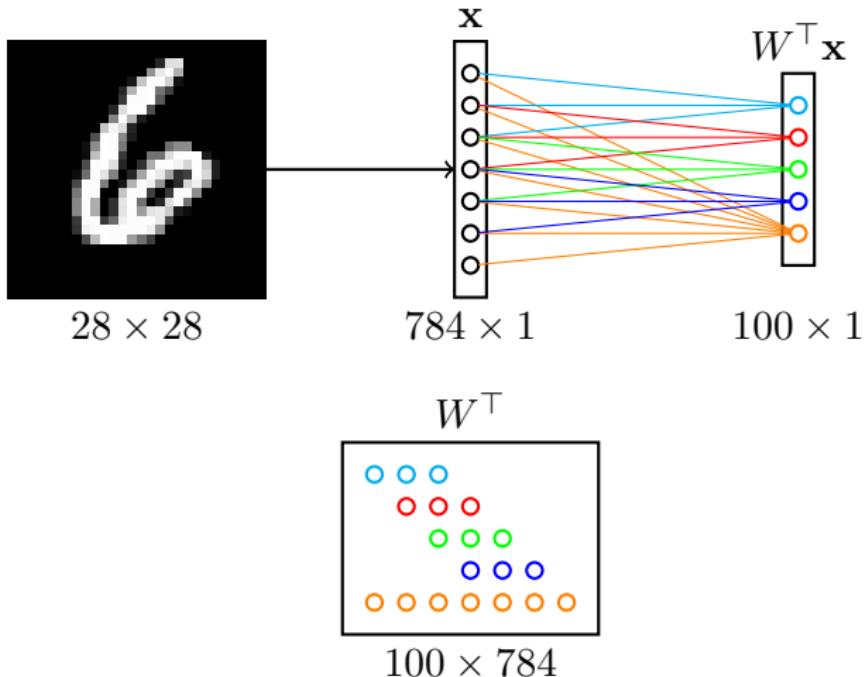

- now, we only keep a **sparse** set of connections
- and matrix W becomes sparse as well

sparse connections

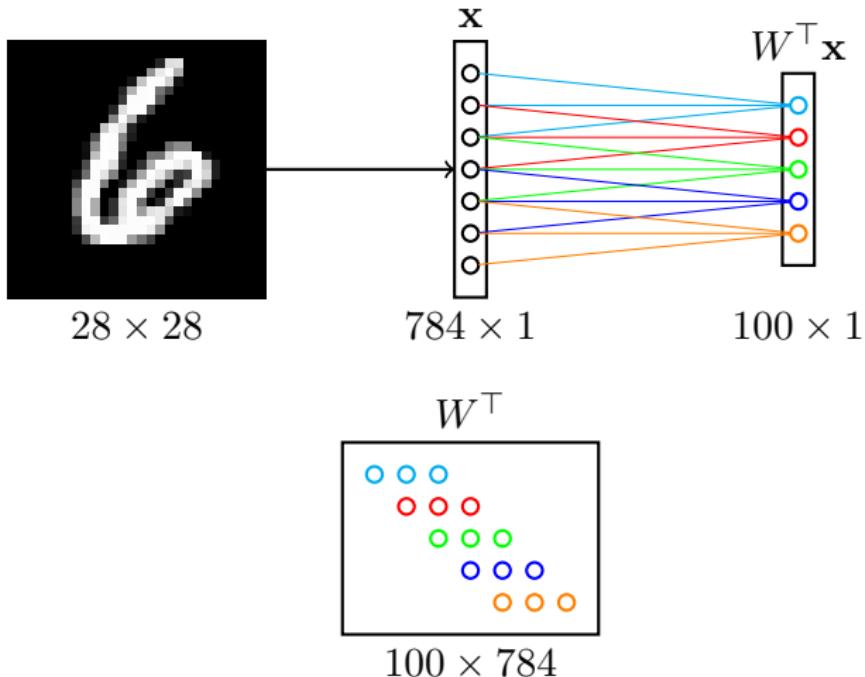

- now, we only keep a **sparse** set of connections
- and matrix W becomes sparse as well

sparse connections

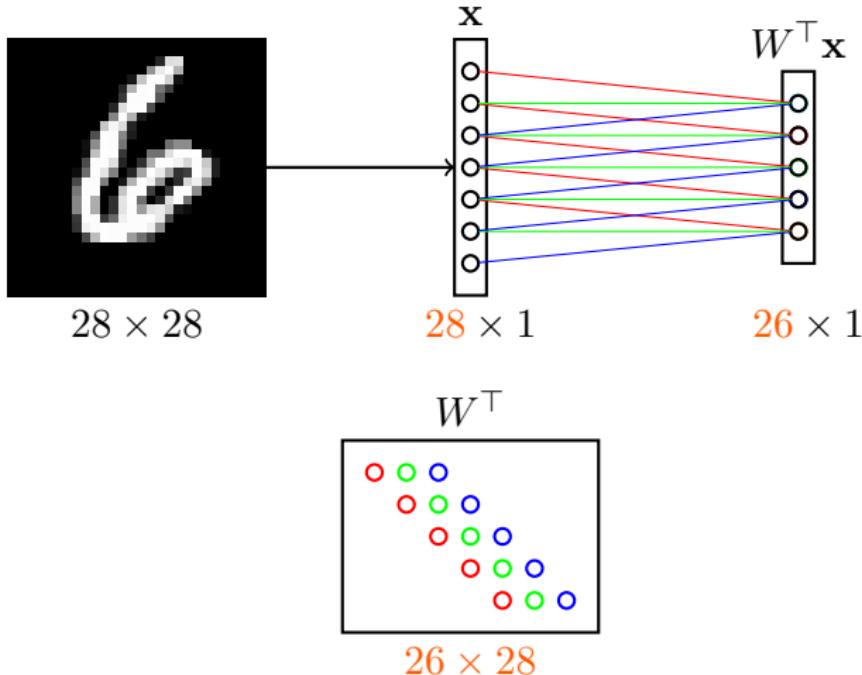

- now, we only keep a **sparse** set of connections
- and matrix W becomes sparse as well

sparse connections

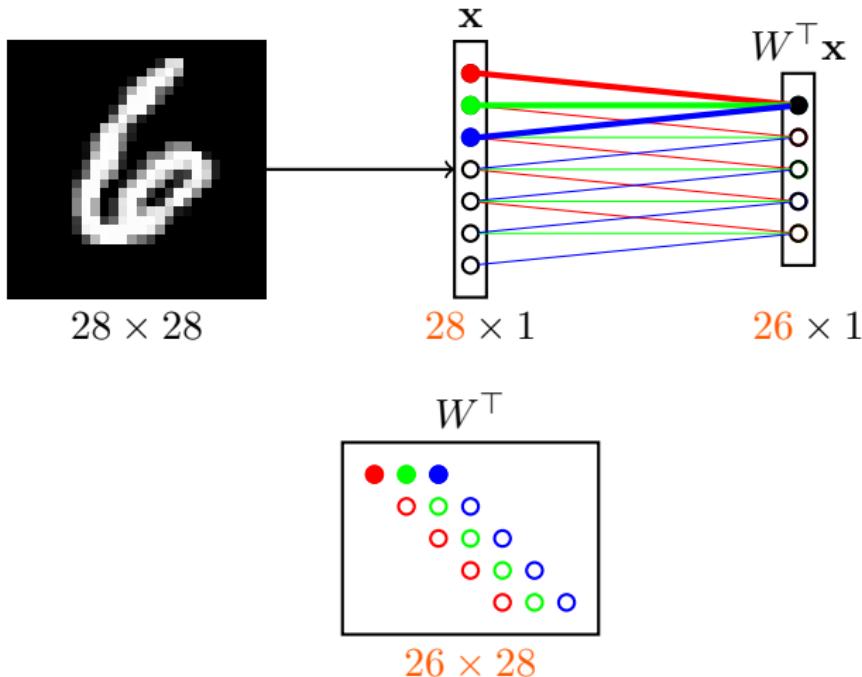

- now, we only keep a **sparse** set of connections
- and matrix W becomes sparse as well

Toeplitz matrix

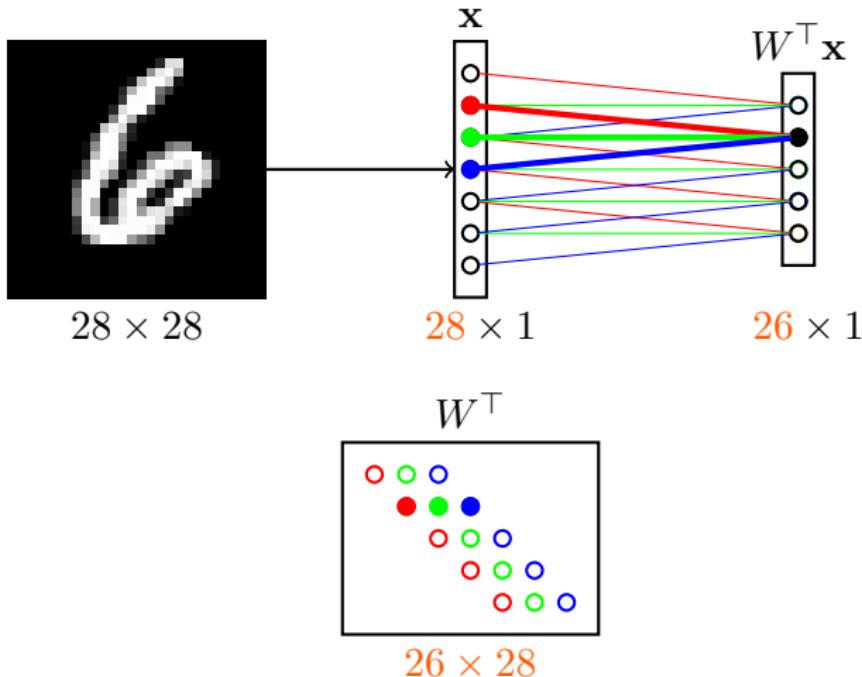

- now, we only refer to one input column; we will repeat
- and all weights having the same color are made equal (**shared**)

Toeplitz matrix \rightarrow convolution

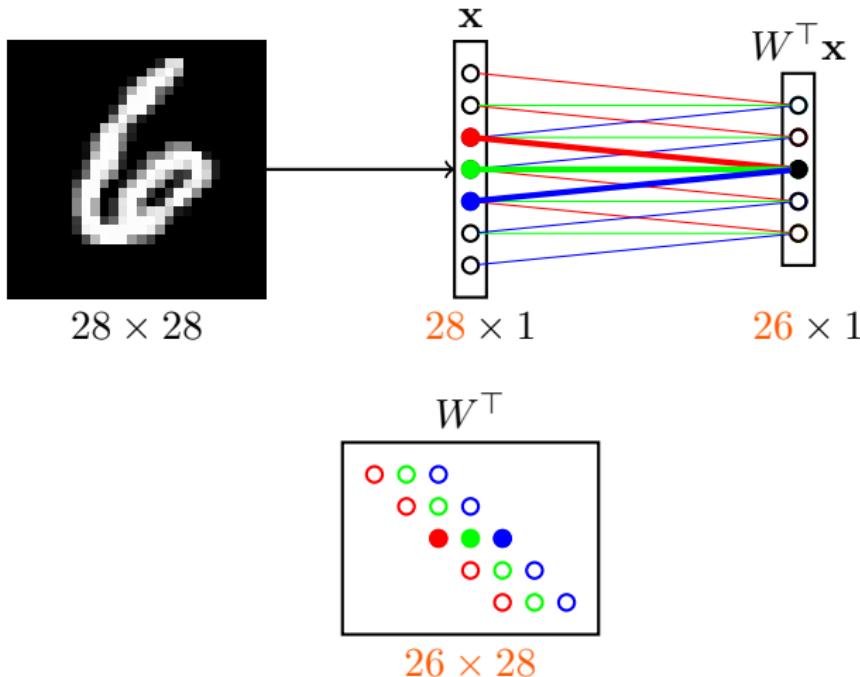

- this can be seen as **shifting** the same weight triplet (**kernel**)
- the set of inputs seen by each cell is its **receptive field**

Toeplitz matrix \rightarrow convolution

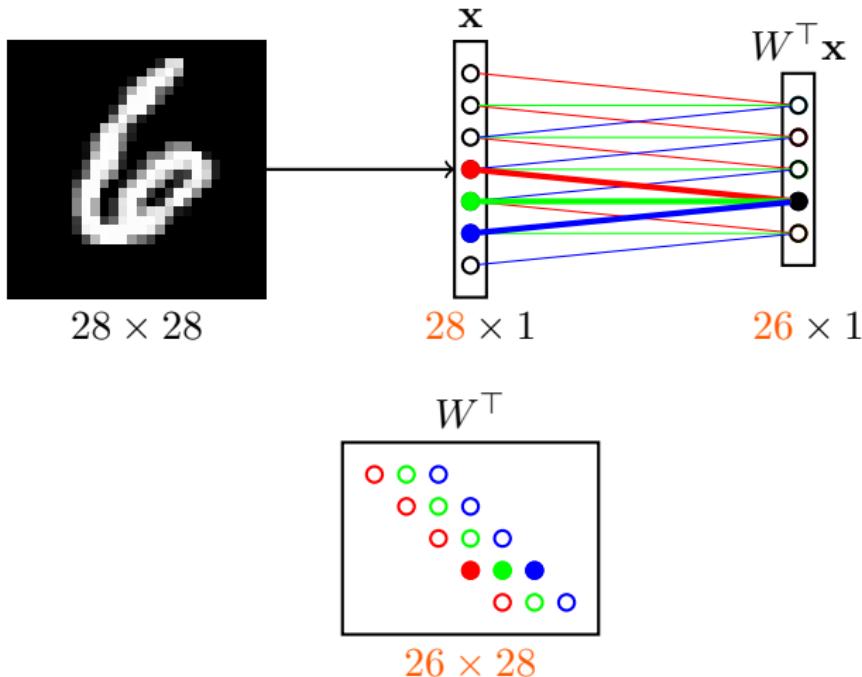

- this can be seen as **shifting** the same weight triplet (**kernel**)
- the set of inputs seen by each cell is its **receptive field**

Toeplitz matrix \rightarrow convolution

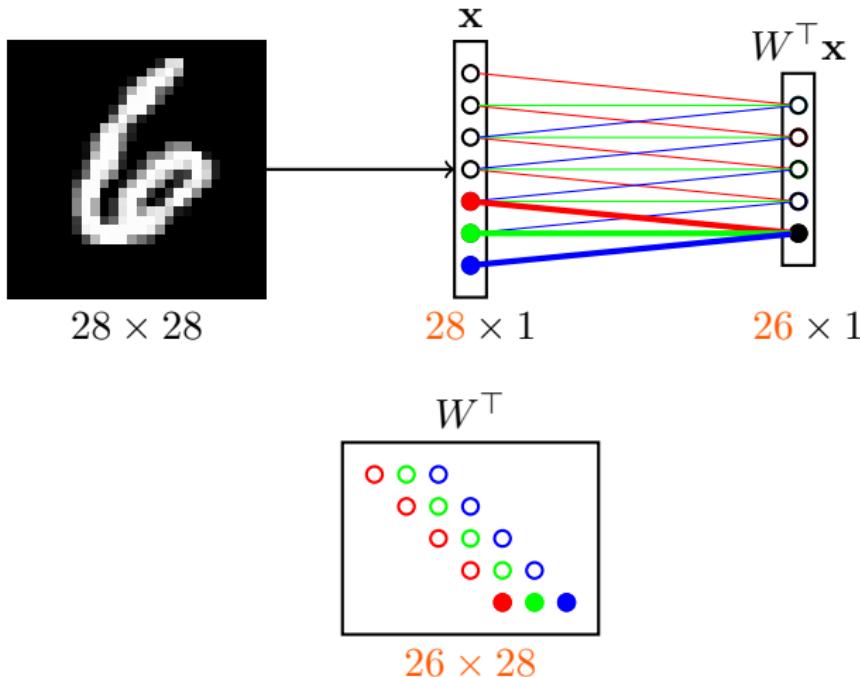

- this can be seen as **shifting** the same weight triplet (**kernel**)
- the set of inputs seen by each cell is its **receptive field**

Toeplitz matrix \rightarrow convolution

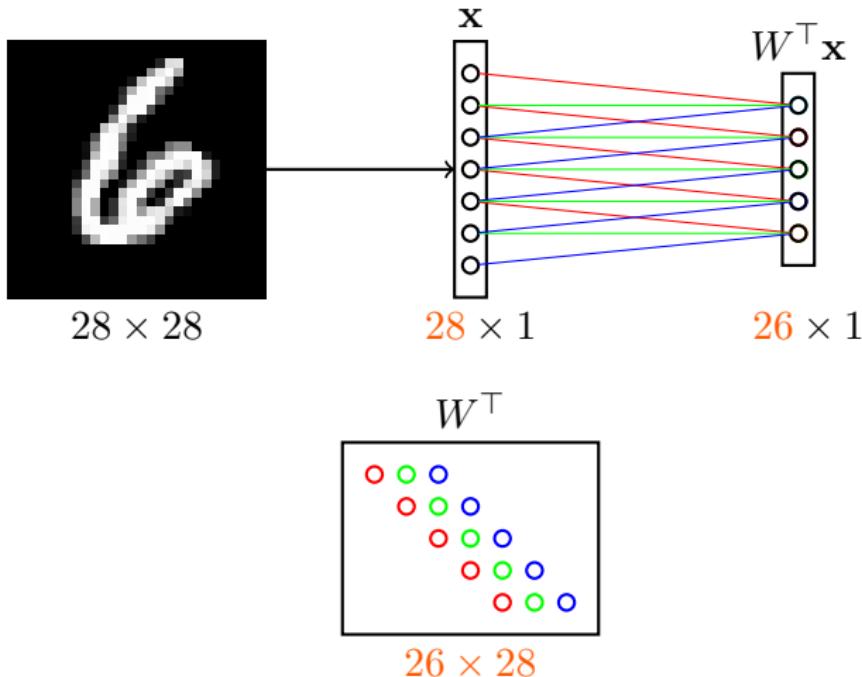

- this can be seen as **shifting** the same weight triplet (**kernel**)
- the set of inputs seen by each cell is its **receptive field**

Toeplitz matrix \rightarrow convolution

- this can be seen as **shifting** the same weight triplet (**kernel**)
- the set of inputs seen by each cell is its **receptive field**

Toeplitz matrix \rightarrow convolution

- this is an 1d **convolution** and generalizes to 2d
- this new mapping is a **convolutional layer**

convolutional networks

convolutional layer

- 1 still linear, still matrix multiplication, just constrained
- 2 local receptive fields → sparse connections between units
- 3 translation equivariant → shared weights
- 4 sparse + shared → regularized: less parameters to learn

convolutional network

- a network of convolutional layers, optionally followed by fully-connected layers
- performs better (less than 1% error on MNIST), but not on shuffled input

convolutional networks

convolutional layer

- 1 still linear, still matrix multiplication, just constrained
- 2 local receptive fields → sparse connections between units
- 3 translation equivariant → shared weights
- 4 sparse + shared → regularized: less parameters to learn

convolutional network

- a network of convolutional layers, optionally followed by fully-connected layers
- performs better (less than 1% error on MNIST), but not on shuffled input

- 4 sparse + shared → regularized: less parameters to learn

convolutional network

- a network of convolutional layers, optionally followed by fully-connected layers
- performs better (less than 1% error on MNIST), but not on shuffled input

definition and properties

linear time-invariant (LTI) system

- discrete-time **signal**: $x[n]$, $n \in \mathbb{Z}$
- **system** (filter): $f(x)[n]$, $n \in \mathbb{Z}$
- **translation** (or shift, or delay): $s_k(x)[n] = x[n - k]$, $k \in \mathbb{Z}$
- **linear system**: commutes with linear combination

$$f\left(\sum_i a_i x_i\right) = \sum_i a_i f(x_i)$$

- **time-invariant** system: commutes with translation

$$f(s_k(x)) = s_k(f(x))$$

linear time-invariant (LTI) system

- discrete-time **signal**: $x[n]$, $n \in \mathbb{Z}$
- **system** (filter): $f(x)[n]$, $n \in \mathbb{Z}$
- **translation** (or shift, or delay): $s_k(x)[n] = x[n - k]$, $k \in \mathbb{Z}$
- **linear system**: commutes with linear combination

$$f \left(\sum_i a_i x_i \right) = \sum_i a_i f(x_i)$$

- **time-invariant** system: commutes with translation

$$f(s_k(x)) = s_k(f(x))$$

LTI system \equiv convolution

- unit impulse $\delta[n] = \mathbb{1}[n = 0]$
- every signal x expressed as

$$x[n] = \sum_k x[k]\delta[n - k] = \sum_k x[k]s_k(\delta)[n]$$

- if f is LTI with impulse response $h = f(\delta)$, then $f(x) = x * h$:

$$\begin{aligned}f(x)[n] &= f\left(\sum_k x[k]s_k(\delta)\right)[n] = \sum_k x[k]s_k(f(\delta))[n] \\&= \sum_k x[k]h[n - k] = x * h[n]\end{aligned}$$

LTI system \equiv convolution

- unit impulse $\delta[n] = \mathbb{1}[n = 0]$
- every signal x expressed as

$$x[n] = \sum_k x[k]\delta[n - k] = \sum_k x[k]s_k(\delta)[n]$$

- if f is LTI with impulse response $h = f(\delta)$, then $f(x) = x * h$:

$$\begin{aligned}f(x)[n] &= f\left(\sum_k x[k]s_k(\delta)\right)[n] = \sum_k x[k]s_k(f(\delta))[n] \\&= \sum_k x[k]h[n - k] := (x * h)[n]\end{aligned}$$

LTI system \equiv convolution

- unit impulse $\delta[n] = \mathbb{1}[n = 0]$
- every signal x expressed as

$$x[n] = \sum_k x[k]\delta[n - k] = \boxed{\sum_k x[k]s_k(\delta)[n]}$$

- if f is LTI with impulse response $h = f(\delta)$, then $f(x) = x * h$:

$$\begin{aligned} f(x)[n] &= f \left(\sum_k x[k]s_k(\delta) \right) [n] = \sum_k x[k]s_k(f(\delta))[n] \\ &= \sum_k x[k]h[n - k] := (x * h)[n] \end{aligned}$$

LTI system \equiv convolution

- unit impulse $\delta[n] = \mathbb{1}[n = 0]$
- every signal x expressed as

$$x[n] = \sum_k x[k]\delta[n - k] = \sum_k x[k]s_k(\delta)[n]$$

- if f is LTI with impulse response $h = f(\delta)$, then $f(x) = x * h$:

$$\begin{aligned} f(x)[n] &= \boxed{f} \left(\sum_k x[k]s_k(\delta) \right) [n] = \sum_k x[k]s_k(\boxed{f(\delta)})[n] \\ &= \sum_k x[k]h[n - k] := (x * h)[n] \end{aligned}$$

LTI system \equiv convolution

- unit impulse $\delta[n] = \mathbb{1}[n = 0]$
- every signal x expressed as

$$x[n] = \sum_k x[k]\delta[n - k] = \sum_k x[k]s_k(\delta)[n]$$

- if f is LTI with impulse response $h = f(\delta)$, then $f(x) = x * h$:

$$f(x)[n] = f \left(\sum_k x[k]s_k(\delta) \right) [n] = \sum_k x[k]s_k(f(\delta))[n]$$

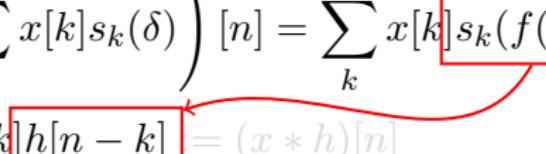

$$= \sum_k x[k]h[n - k] := (x * h)[n]$$

LTI system \equiv convolution

- unit impulse $\delta[n] = \mathbb{1}[n = 0]$
- every signal x expressed as

$$x[n] = \sum_k x[k]\delta[n - k] = \sum_k x[k]s_k(\delta)[n]$$

- if f is LTI with impulse response $h = f(\delta)$, then $f(x) = x * h$:

$$\begin{aligned} f(x)[n] &= f\left(\sum_k x[k]s_k(\delta)\right)[n] = \sum_k x[k]s_k(f(\delta))[n] \\ &= \sum_k x[k]h[n - k] = (x * h)[n] \end{aligned}$$

LTI system \equiv convolution

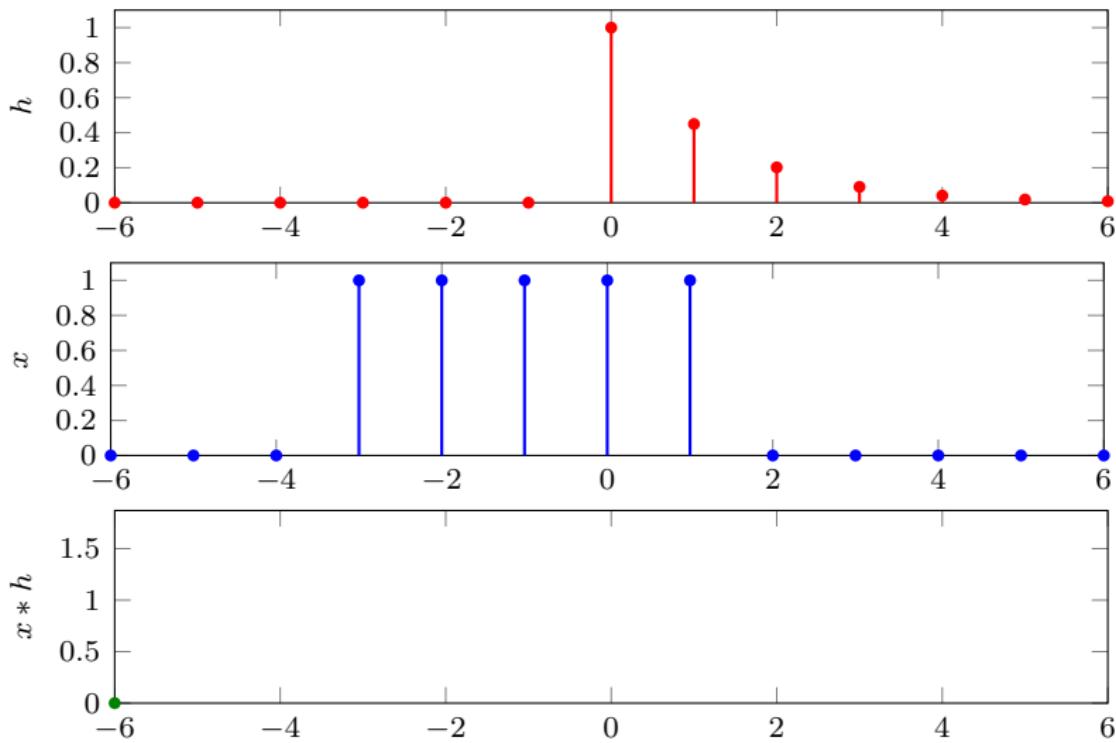

- unit impulse $\delta[n] = \mathbb{1}[n = 0]$
- every signal x expressed as

$$x[n] = \sum_k x[k]\delta[n - k] = \sum_k x[k]s_k(\delta)[n]$$

invariance vs. equivariance

- time invariance: invariance to **absolute** time (or position)
- translation (or shift) equivariance: equivariance to **relative** time (or position)
- despite confusion, both mean the same thing: **system commutes with translation**

$$f(s_k(x)) = s_k(f(x))$$

however

- translation (or shift) invariance, means that for all k ,

$$f(s_k(x)) = f(x)$$

- each convolutional layer is translation equivariant; but **pooling** makes a network translation invariant, e.g.

$$\sum_n s_k(x)[n] = \sum_n x[n - k] = \sum_n x[n]$$

invariance vs. equivariance

- time invariance: invariance to **absolute** time (or position)
- translation (or shift) equivariance: equivariance to **relative** time (or position)
- despite confusion, both mean the same thing: **system commutes with translation**

$$f(s_k(x)) = s_k(f(x))$$

however

- translation (or shift) invariance, means that for all k ,

$$f(s_k(x)) = f(x)$$

- each convolutional layer is translation equivariant; but **pooling** makes a network translation invariant, e.g.

$$\sum_n s_k(x)[n] = \sum_n x[n - k] = \sum_n x[n]$$

finite impulse response (FIR)

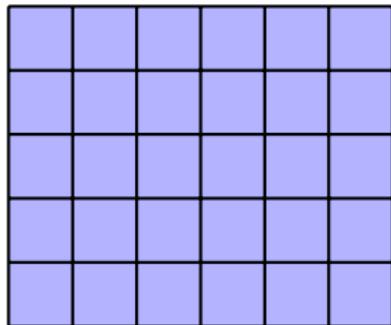

- an FIR system has impulse response h of finite duration (or spatial extent), because it settles to zero in finite time (extent) from the input impulse
- “sparse connections and local receptive fields” mean exactly that h is of finite duration (extent)
- we assume this in the following, starting with a 2d extension, where we write $x[\mathbf{n}]$, $\mathbf{n} \in \mathbb{Z}^2$

2d convolution

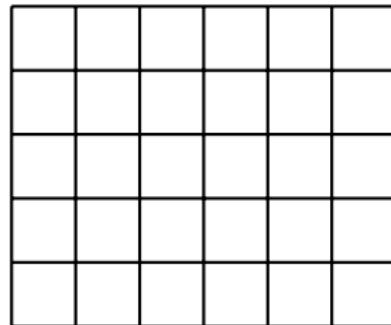

1	2	3

7	8	9

h

$$(x * h)[\mathbf{n}] = \sum_{\mathbf{k}} x[\mathbf{k}]h[\mathbf{n} - \mathbf{k}]$$
$$= \sum_{\mathbf{k}} h[\mathbf{k}]x[\mathbf{n} - \mathbf{k}]$$

x

$x * h$

2d convolution

1	2	3
4	5	6
7	8	9

h

$$(x * h)[\mathbf{n}] = \sum_{\mathbf{k}} x[\mathbf{k}]h[\mathbf{n} - \mathbf{k}]$$

$$= \sum_{\mathbf{k}} h[\mathbf{k}]x[\mathbf{n} - \mathbf{k}]$$

x

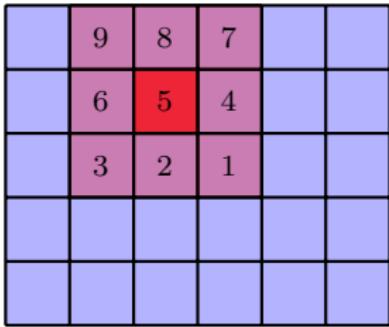

$x * h$

2d convolution

$$\begin{array}{|c|c|c|} \hline 1 & 2 & 3 \\ \hline 4 & 5 & 6 \\ \hline 7 & 8 & 9 \\ \hline \end{array}$$

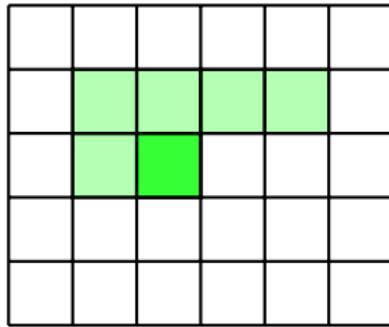

h

$$(x * h)[\mathbf{n}] = \sum_{\mathbf{k}} x[\mathbf{k}]h[\mathbf{n} - \mathbf{k}]$$
$$= \sum_{\mathbf{k}} h[\mathbf{k}]x[\mathbf{n} - \mathbf{k}]$$

A 3x3 input matrix x with values:

9	8	7
6	5	4
3	2	1

x

A 5x5 output matrix $x * h$ with values:

	green	green	green	green
	green	green	green	green

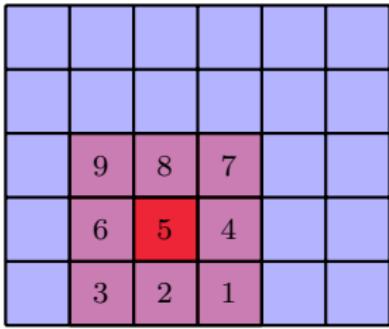

$x * h$

2d convolution

$$\begin{array}{|c|c|c|} \hline 1 & 2 & 3 \\ \hline 4 & 5 & 6 \\ \hline 7 & 8 & 9 \\ \hline \end{array}$$

h

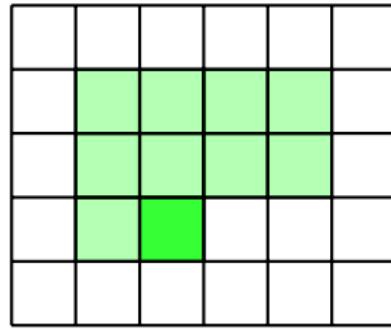

$$(x * h)[\mathbf{n}] = \sum_{\mathbf{k}} x[\mathbf{k}]h[\mathbf{n} - \mathbf{k}]$$
$$= \sum_{\mathbf{k}} h[\mathbf{k}]x[\mathbf{n} - \mathbf{k}]$$

The input image x is a 5x5 grid of blue squares. It contains a 3x3 red kernel with values 9, 8, 7 in the top row, 6, 5, 4 in the middle row, and 3, 2, 1 in the bottom row.

$$\begin{matrix} & & & & \\ & & & & \\ & 9 & 8 & 7 & \\ & 6 & 5 & 4 & \\ & 3 & 2 & 1 & \end{matrix}$$

x

The convolved image $x * h$ is a 5x5 grid. It has a 3x3 green kernel centered on the value 5 of the input. The green kernel's values are 1, 1, 1 in the top row, 1, 1, 1 in the middle row, and 1, 1, 1 in the bottom row. All other positions in the output grid are white.

$$\begin{matrix} & & & & \\ & & & & \\ & 1 & 1 & 1 & \\ & 1 & 1 & 1 & \\ & 1 & 1 & 1 & \end{matrix}$$

$x * h$

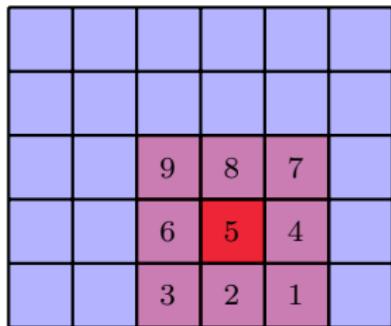

2d convolution

1	2	3
4	5	6
7	8	9

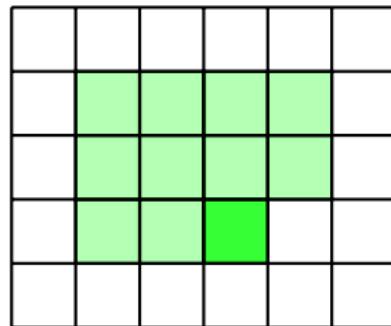

h

$$(x * h)[\mathbf{n}] = \sum_{\mathbf{k}} x[\mathbf{k}]h[\mathbf{n} - \mathbf{k}]$$

$$= \sum_{\mathbf{k}} h[\mathbf{k}]x[\mathbf{n} - \mathbf{k}]$$

x

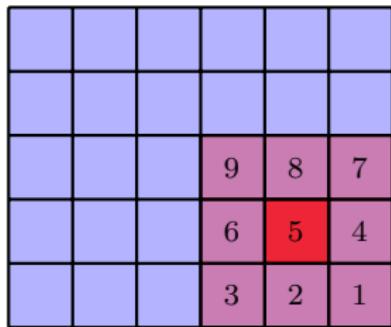

$$x * h$$

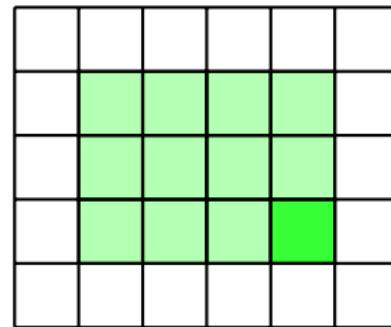

2d convolution

$$h = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{bmatrix}$$

$$(x * h)[\mathbf{n}] = \sum_{\mathbf{k}} x[\mathbf{k}]h[\mathbf{n} - \mathbf{k}]$$
$$= \sum_{\mathbf{k}} h[\mathbf{k}]x[\mathbf{n} - \mathbf{k}]$$

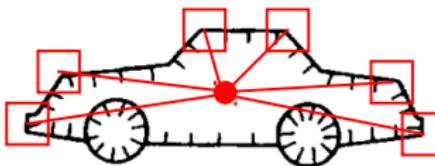

x

$x * h$

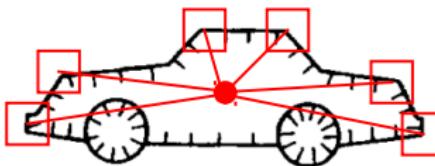

remember Hough in translation space?

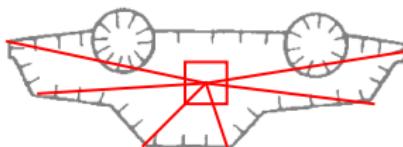

model image

- **model:** record coordinates relative to reference point
- **test:** votes for all possible coordinates of reference point
- impulse response is the **flipped** pattern to be detected

cross-correlation

- convolution is commutative

$$(x * h)[\mathbf{n}] := \sum_{\mathbf{k}} x[\mathbf{k}]h[\mathbf{n} - \mathbf{k}] = \sum_{\mathbf{k}} h[\mathbf{k}]x[\mathbf{n} - \mathbf{k}] = (h * x)[\mathbf{n}]$$

- cross-correlation is not

$$(h \star x)[\mathbf{n}] := \sum_{\mathbf{k}} h[\mathbf{k}]x[\mathbf{k} + \mathbf{n}] = \sum_{\mathbf{k}} x[\mathbf{k}]h[\mathbf{k} - \mathbf{n}] = (x \star h)[-\mathbf{n}]$$

- both are LTI; the only difference is that in cross-correlation, h refers to the flipped impulse response
- but if h is even ($h[n] = h[-n]$), then $h \star x = x * h = h * x$
- in the following, we use cross-correlation $w \star x$ or convolution $x * h$, where $h[n] = w[-n]$ is the impulse response
- we call w the kernel of the operation

cross-correlation

- convolution is commutative

$$(x * h)[\mathbf{n}] := \sum_{\mathbf{k}} x[\mathbf{k}]h[\mathbf{n} - \mathbf{k}] = \sum_{\mathbf{k}} h[\mathbf{k}]x[\mathbf{n} - \mathbf{k}] = (h * x)[\mathbf{n}]$$

- cross-correlation is not

$$(h \star x)[\mathbf{n}] := \sum_{\mathbf{k}} h[\mathbf{k}]x[\mathbf{k} + \mathbf{n}] = \sum_{\mathbf{k}} x[\mathbf{k}]h[\mathbf{k} - \mathbf{n}] = (x \star h)[-\mathbf{n}]$$

- both are LTI; the only difference is that in cross-correlation, h refers to the **flipped** impulse response

features

- something is still missing: so far we had activations \mathbf{a} and outputs \mathbf{y} of the form

$$\mathbf{a} = W^\top \mathbf{x} + \mathbf{b}, \quad \mathbf{y} = h(\mathbf{a}) = h(W^\top \mathbf{x} + \mathbf{b})$$

where \mathbf{x} is the input, $W = (\mathbf{w}_1, \dots, \mathbf{w}_k)$ a weight matrix and \mathbf{b} a bias

- the elements of \mathbf{x} , \mathbf{a} , \mathbf{b} and \mathbf{y} were representing **features** (or cells);
the elements of W were representing **connections**
- now we have x as a 2d array, w as a 2d kernel, but no features yet

feature maps

- now \mathbf{b} remains a vector but \mathbf{x} , \mathbf{a} , \mathbf{y} become **3d tensors** with input feature i and output feature j at spatial position \mathbf{n} represented by

$$x_i[\mathbf{n}], \quad a_j[\mathbf{n}], \quad b_j, \quad y_j[\mathbf{n}]$$

- x_i and y_j are 2d arrays we call **feature maps**, each corresponding to one feature; and a_j a 2d array we call **activation map**
- if x_i refers to the input image, there is just one feature that is the image intensity of a monochrome image, or three features corresponding to the three **channels** of a color image
- W becomes a **4d tensor** with a connection from input feature i to output feature j at spatial position \mathbf{k} represented by

$$w_{ij}[\mathbf{k}]$$

feature maps

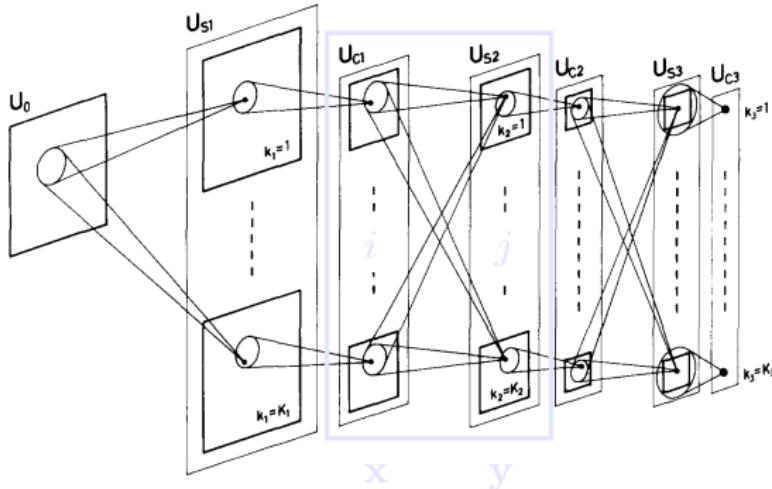

- now \mathbf{b} remains a vector but \mathbf{x} , \mathbf{a} , \mathbf{y} become **3d tensors** with input feature i and output feature j at spatial position \mathbf{n} represented by

$$x_i[\mathbf{n}], \quad a_j[\mathbf{n}], \quad b_j, \quad y_j[\mathbf{n}]$$

- x_i and y_j are 2d arrays we call **feature maps**, each corresponding to one feature; and a_j a 2d array we call **activation map**
- if x_i refers to the input image, there is just one feature that is the image intensity of a monochrome image, or three features corresponding to the three **channels** of a color image
- W becomes a **4d tensor** with a connection from input feature i to output feature j at spatial position \mathbf{k} represented by

$$w_{ij}[\mathbf{k}]$$

convolution on feature maps

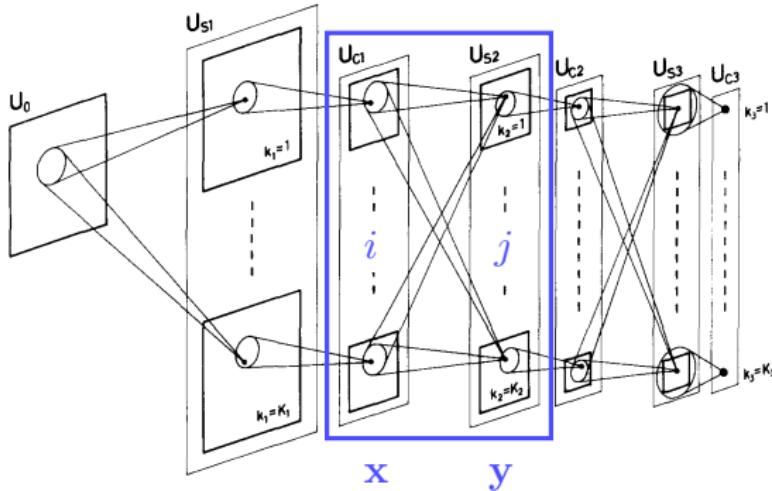

- matrix multiplication and convolution combined

$$\mathbf{a} = W^T \star \mathbf{x} + \mathbf{b}, \quad \mathbf{y} = h(\mathbf{a}) = h(W^T \star \mathbf{x} + \mathbf{b})$$

$$(W^T \star \mathbf{x})_j[n] = (\mathbf{w}_j^T \star \mathbf{x})[n] := \sum_i (w_{ij} \star x_i)[n] = \sum_k w_{ij}[k] x_i[k+n]$$

convolution on feature maps

convolution as regularization

- suppose a fully connected layer is given by

$$\mathbf{a} = \begin{pmatrix} w_1 & w_2 & w_3 \\ w_4 & w_5 & w_6 \end{pmatrix} \mathbf{x}$$

- now if we add the following term to our error function

$$\frac{\lambda}{2} ((w_6 - w_2)^2 + (w_5 - w_1)^2 + w_3^2 + w_4^2)$$

then, as $\lambda \rightarrow \infty$, the weight matrix tends to the constrained **Toeplitz** form

$$\begin{pmatrix} w_1 & w_2 & 0 \\ 0 & w_1 & w_2 \end{pmatrix}$$

and the layer becomes **convolutional**

convolution as regularization

- suppose a fully connected layer is given by

$$\mathbf{a} = \begin{pmatrix} w_1 & w_2 & w_3 \\ w_4 & w_5 & w_6 \end{pmatrix} \mathbf{x}$$

- now if we add the following term to our error function

$$\frac{\lambda}{2} ((w_6 - w_2)^2 + (w_5 - w_1)^2 + w_3^2 + w_4^2)$$

then, as $\lambda \rightarrow \infty$, the weight matrix tends to the constrained **Toeplitz** form

$$\begin{pmatrix} w_1 & w_2 & 0 \\ 0 & w_1 & w_2 \end{pmatrix}$$

and the layer becomes **convolutional**

convolution as Gaussian mixture prior

- remember, weight decay is equivalent to a zero-centered Gaussian prior if the weight vector/matrix is considered a random variable
- in this analogy, error term

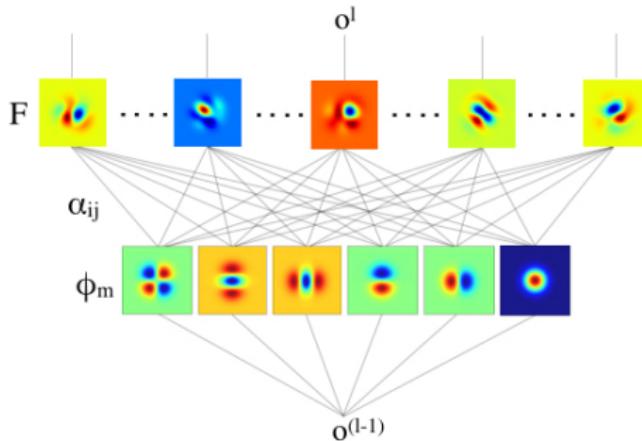

$$\frac{\lambda}{2} ((w_6 - w_2)^2 + (w_5 - w_1)^2 + w_3^2 + w_4^2)$$

corresponds to two Gaussian priors centered at w_1 , w_2 for w_5 , w_6 and one zero-centered Gaussian for w_3 , w_4

- that is, a Gaussian mixture prior

structured convolution

[Jacobsen et al. 2016]

- we can constrain parameters even more by considering a fixed basis of **steerable filters** consisting of **separable Gaussian derivatives**
 - the network then only learns the parameters needed to construct a filter as a linear combination of the basis filters
 - this applies to all layers

variants and their derivatives

convolution variants

- we will examine a number of variants of convolution, each only in one dimension
- this leaves an extension to one more spatial dimension (convolution), and one more feature dimension (matrix multiplication)
- in each case, we will write convolution as matrix multiplication, where the matrix has some special structure: derivatives are then straightforward

standard convolution

- input size n , kernel size r , output size n'

$$x \quad \begin{array}{|c|c|c|c|c|c|c|} \hline \textcolor{blue}{\square} & \textcolor{blue}{\square} & \textcolor{blue}{\square} & \textcolor{blue}{\square} & \textcolor{blue}{\square} & \textcolor{blue}{\square} & \textcolor{blue}{\square} \\ \hline \end{array} \quad n = 7, r = 3$$

$$h' = \lfloor (h + 2p - \hat{r})/s \rfloor + 1$$

- r^2kk' weights, k' biases, $(r^2k + 1)k'$ **parameters** in total
- $(r^2k + 1)v' = (r^2k + 1)k' \times w' \times h'$ **operations** in total

pooling

spatial pooling

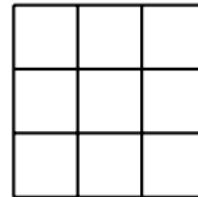

- the deeper a layer is, the larger becomes the **receptive field** of each cell and the **density** of cells decreases accordingly
- gradually introduces translation and deformation **invariance**
- pooling is **independent** per feature map and connections are **fixed**

spatial pooling

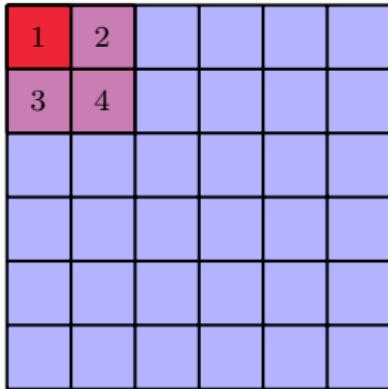

$$n = 6, r = 2, s = 2$$

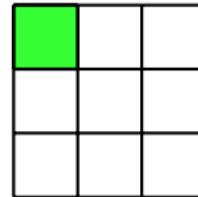

$$n' = \lfloor n/s \rfloor = 3$$

- same “sliding window” as in convolution, only has **no parameters** and performs orderless pooling rather than dot product per neighborhood, e.g. average or max
- no padding but usually stride $s > 1$
- typically, $r = s$ such that $n' = \lfloor (n - r)/s \rfloor + 1 = \lfloor n/s \rfloor$

spatial pooling

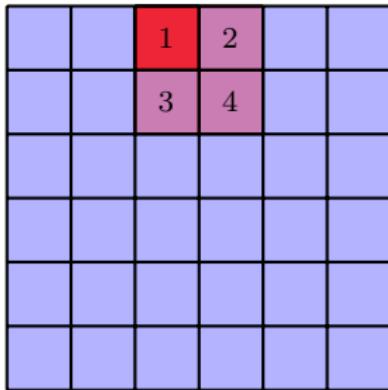

$$n = 6, r = 2, s = 2$$

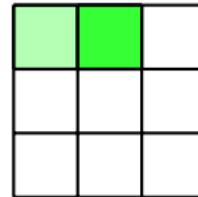

$$n' = \lfloor n/s \rfloor = 3$$

- same “sliding window” as in convolution, only has **no parameters** and performs orderless pooling rather than dot product per neighborhood, e.g. average or max
- no padding but usually stride $s > 1$
- typically, $r = s$ such that $n' = \lfloor (n - r)/s \rfloor + 1 = \lfloor n/s \rfloor$

spatial pooling

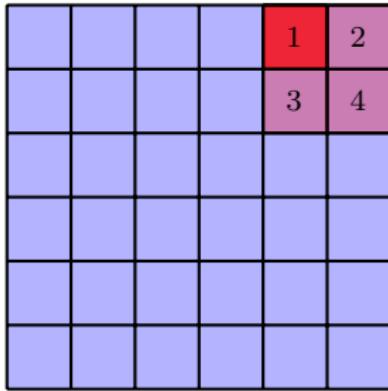

$$n = 6, r = 2, s = 2$$

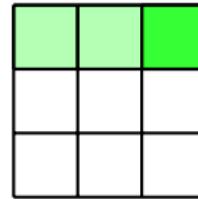

$$n' = \lfloor n/s \rfloor = 3$$

- same “sliding window” as in convolution, only has **no parameters** and performs orderless pooling rather than dot product per neighborhood, e.g. average or max
- no padding but usually stride $s > 1$
- typically, $r = s$ such that $n' = \lfloor (n - r)/s \rfloor + 1 = \lfloor n/s \rfloor$

spatial pooling

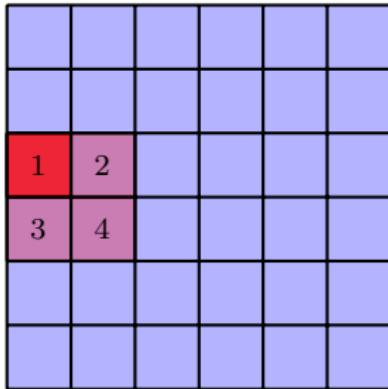

$$n = 6, r = 2, s = 2$$

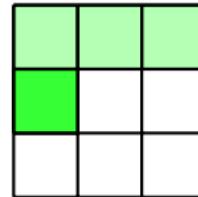

$$n' = \lfloor n/s \rfloor = 3$$

$$n' = \lfloor n/s \rfloor = 3$$

- same “sliding window” as in convolution, only has **no parameters** and performs orderless pooling rather than dot product per neighborhood, e.g. average or max
- no padding but usually stride $s > 1$
- typically, $r = s$ such that $n' = \lfloor (n - r)/s \rfloor + 1 = \lfloor n/s \rfloor$

feature pooling e.g. maxout

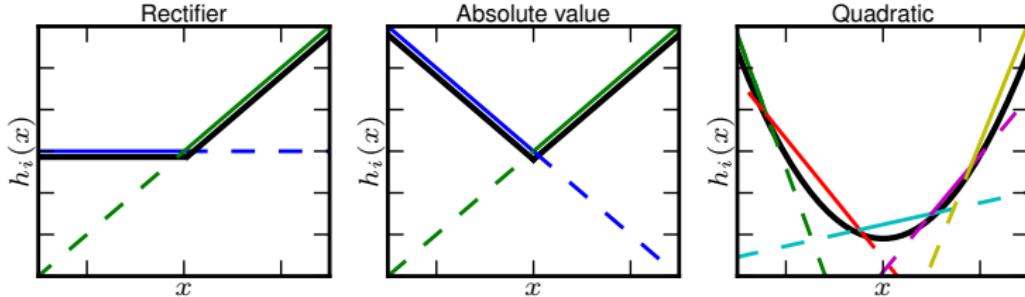

- unlike most activation functions that are element-wise, maxout groups several (e.g. k) activations together and takes their maximum

$$a = \max_j \mathbf{w}_j^\top \mathbf{x} + b_j$$

- does not saturate or “die”, but increases the cost by k
- can approximate any convex function
- two such units can approximate any smooth function!

feature pooling e.g. maxout

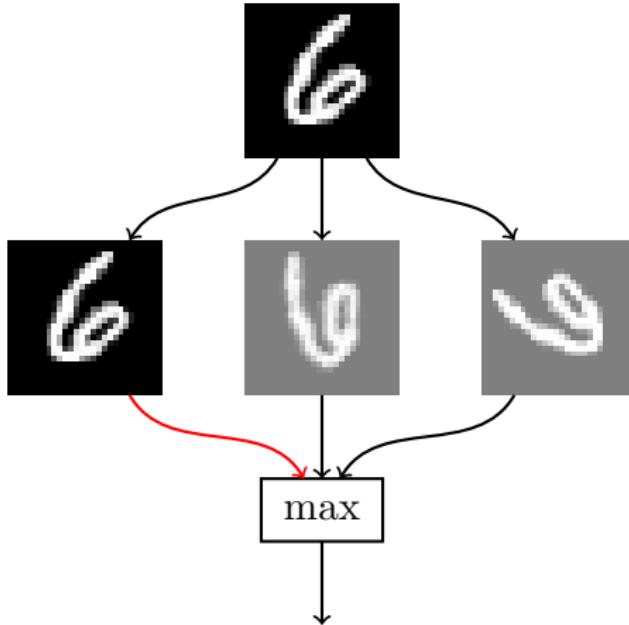

- unlike most activation functions that are element-wise, maxout groups several (e.g. k) activations together and takes their maximum

$$a = \max_j \mathbf{w}_j^\top \mathbf{x} + b_j$$

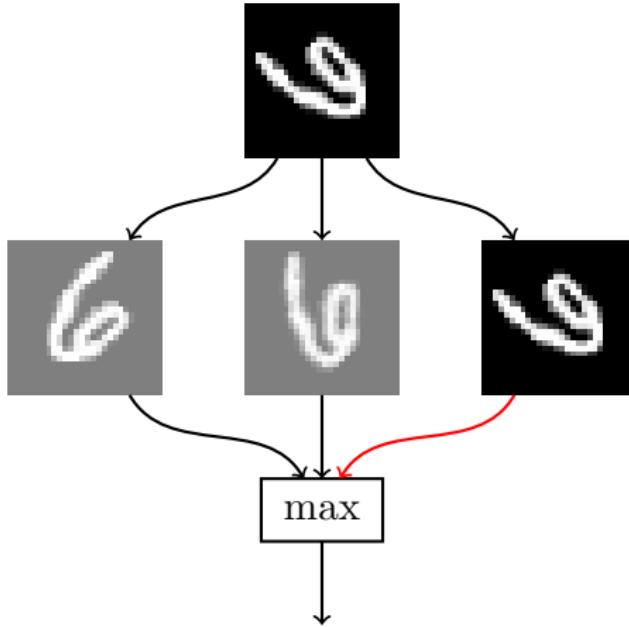

- does not saturate or “die”, but increases the cost by k
- can approximate any convex function
- two such units can approximate any smooth function!

feature pooling: pose invariance

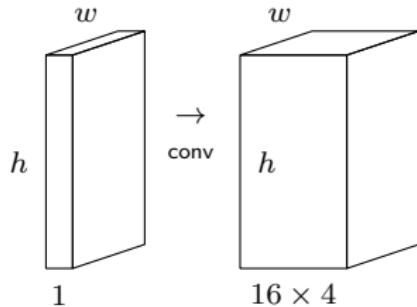

- if each activation responds to a different pose or view, maxout will respond to any

feature pooling: pose invariance

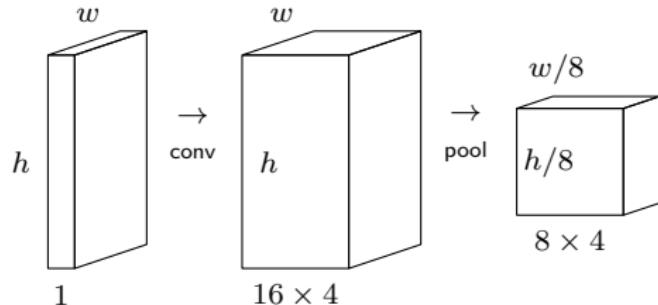

- if each activation responds to a different pose or view, maxout will respond to any

remember HMAX?

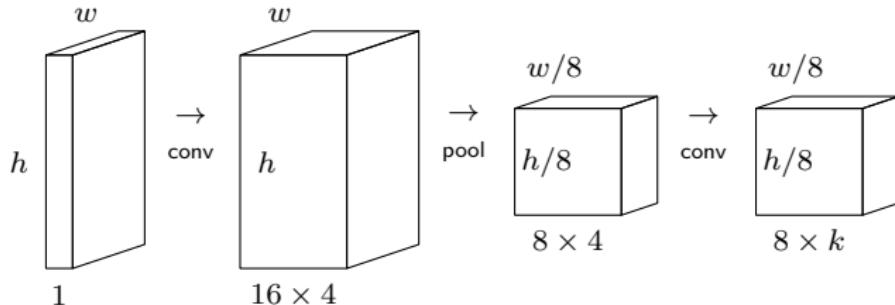

- apply filters at 16 scales \times 4 orientations
- max-pooling over 8×8 spatial cells and over 2 scales
- convolutional RBF matching of input patches X to $k = 4072$ prototypes P (4×4 patches at 4 orientations) extracted at random during learning: activation $Y = \exp(-\gamma \|X - P\|^2)$
- global max pooling over positions and scales
- orientations are not pooled

pool(3, 2)	0	43,264	$6 \times 6 \times 256$
fc(4096)	37,752,832	37,752,832	4,096
fc(4096)	16,781,312	16,781,312	4,096
fc(1000)	4,097,000	4,097,000	1,000
softmax	0	1,000	1,000

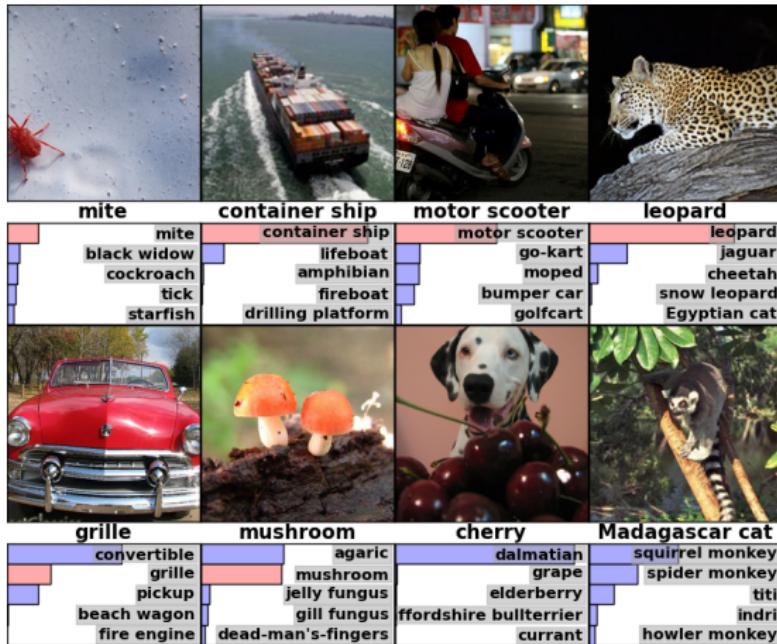

- ReLU follows each convolutional and fully connected layer
- CaffeNet: input size modified from 224×224 , pool/norm switched

AlexNet: classification examples

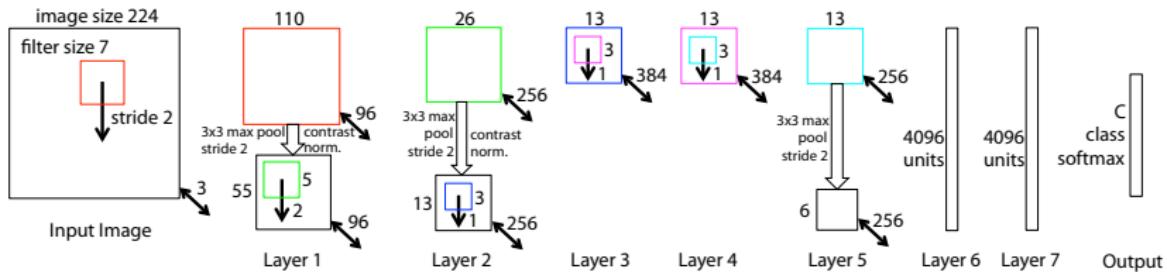

- correct label on top; its predicted probability with red if visible

ImageNet classification performance

ZFNet

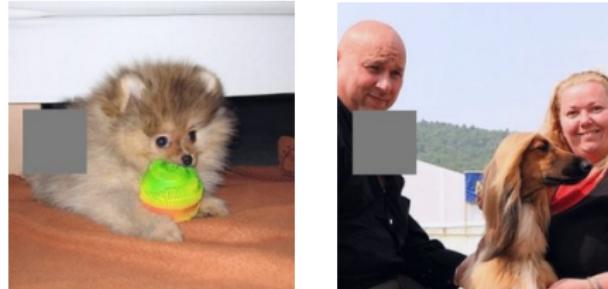

- 11.7% top-5 error on ILSVRC'13
 - 8 layers, refinement of AlexNet
 - layer 1 kernel size (stride) reduced from 11(4) to 7(2) to reduce aliasing artifacts
 - conv3,4,5 width increased to 512, 1024, 512

ZFNet

	parameters	operations	volume
input(224, 3)	0	0	$224 \times 224 \times 3$
conv(7, 96, s2, p1)	14,208	171,916,800	$110 \times 110 \times 96$

fc(4096)	16,781,312	16,781,312	4,096
fc(1000)	4,097,000	4,097,000	1,000
softmax	0	1,000	1,000

- layer widths adjusted by cross-validation; **depth matters**

ZFNet: occlusion sensitivity

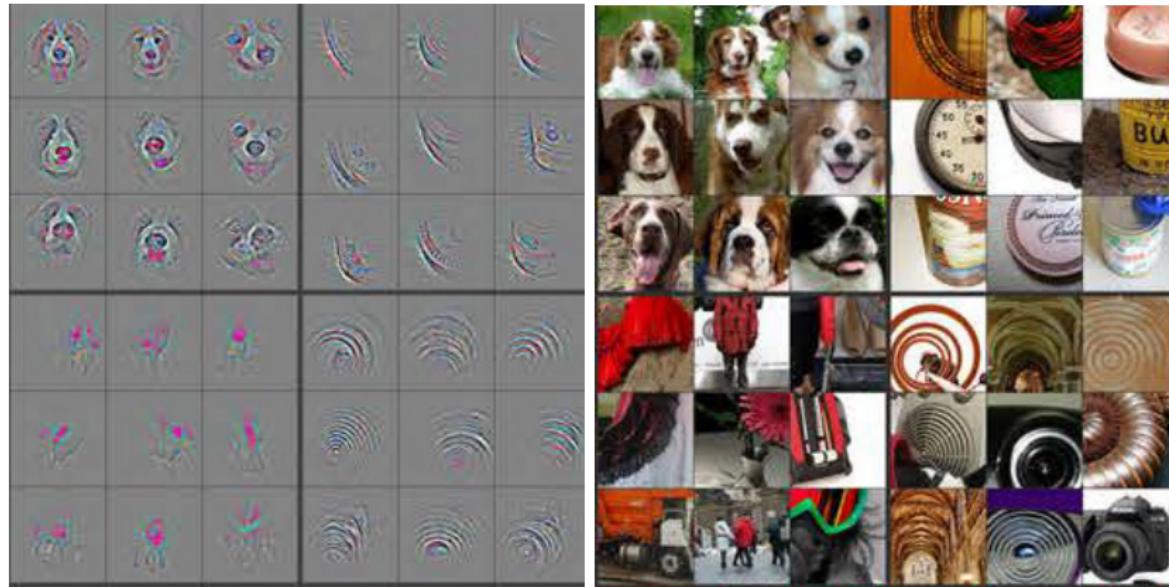

image

correct class probability

- image occluded by gray square
- correct class probability as a function of the position of the square

ZFNet: visualizing intermediate layers

- reconstructed patterns from top 9 activations of selected features of layer 4 and corresponding image patches

VGG

maxpool					

- 7.3% top-5 error on ILSVRC'14
- depth increased up to 19 layers, kernel sizes (strides) reduced to 3(1)
- local response normalization doesn't do anything
- top/bottom layers of deep models pre-initialized by trained model A

effective receptive field

L_0

L_1

L_2

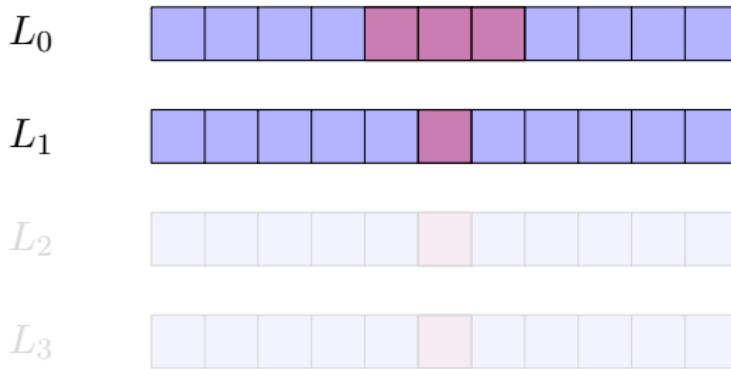

L_3

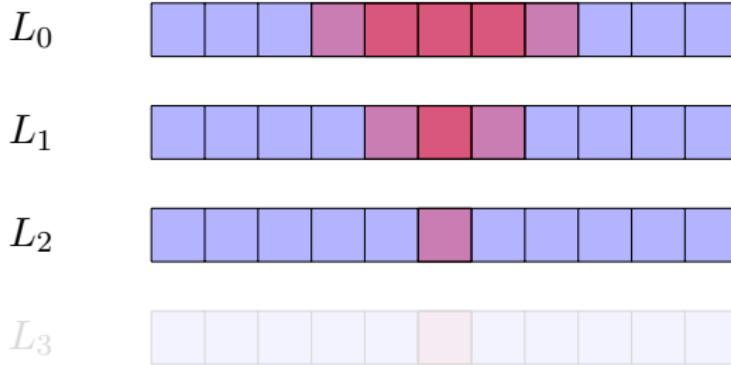

- is the part of the visual input that affects a given cell indirectly through previous layers
- grows linearly with depth
- stack of three 3×3 kernels of stride 1 has the same effective receptive field as a single 7×7 kernel, but fewer parameters

effective receptive field

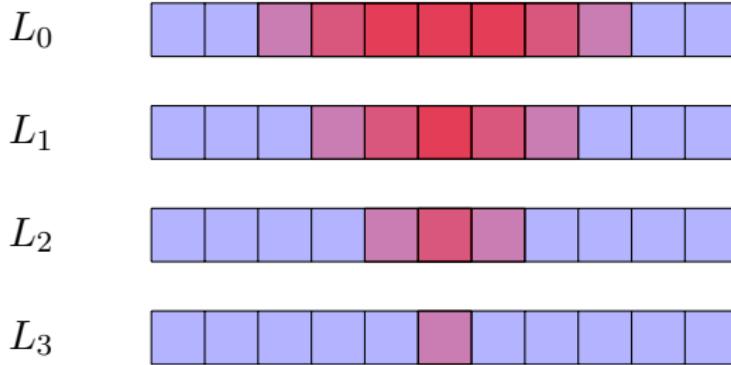

- is the part of the visual input that affects a given cell indirectly through previous layers
- grows linearly with depth
- stack of three 3×3 kernels of stride 1 has the same effective receptive field as a single 7×7 kernel, but fewer parameters

WE NEED TO GO

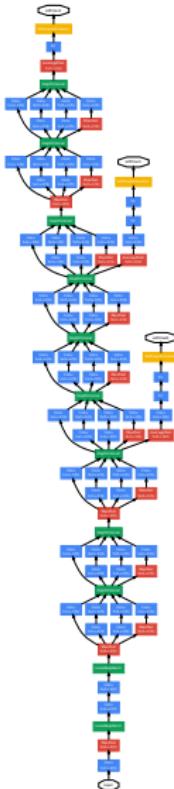

DEEPER

ImageNet classification performance

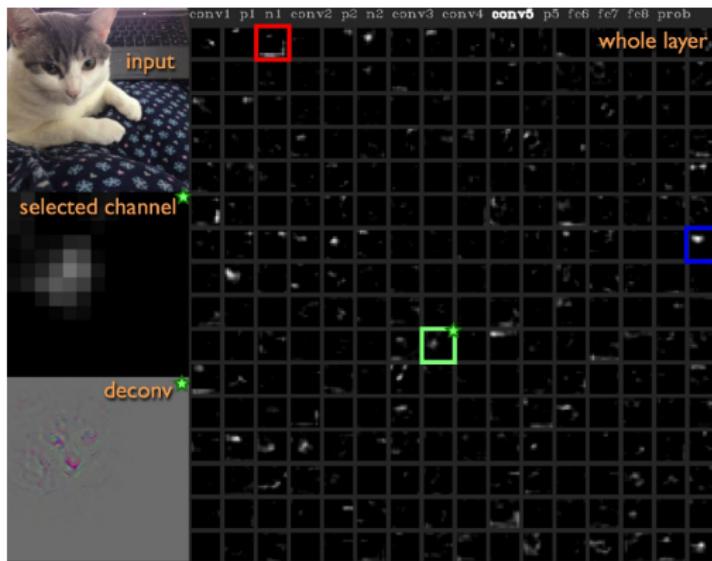

GoogLeNet

[Szegedy et al. 2015]

- 6.7% top-5 error on ILSVRC'14
- depth increased to 22 layers, kernel sizes 1×1 to 5×5
- inception module repeated 9 times
- 1×1 kernels used as “bottleneck” layers (dimensionality reduction)
- 25 times less parameters and faster than AlexNet
- auxiliary classifiers

convolutional features are sparse

- remember, features play the role of codebooks, and bag-of-words representations can be sparse even **after pooling**
 - with relu, each feature represents a “**detector**” that fires when the activation is positive

convolutional features are sparse

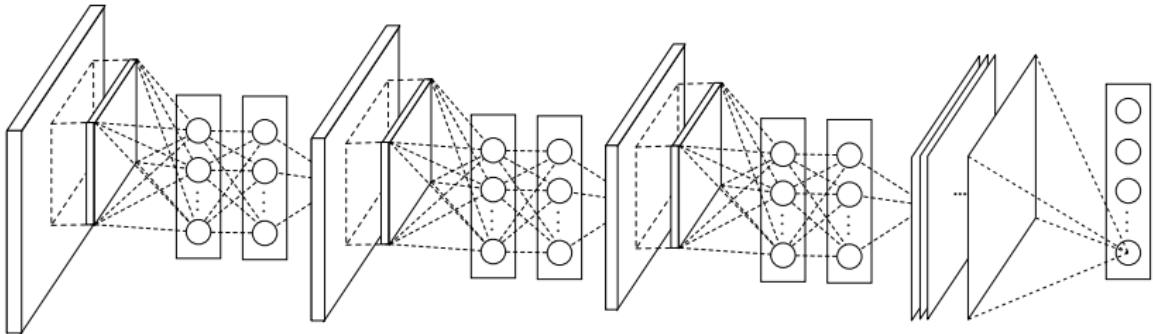

- deep layers have more features (e.g. 1024) and lower resolutions (e.g. 7×7)
 - detected patterns in many cases are as small as 5×5 , 3×3 or even 1×1
 - the convolution operation resembles more (sparse) matrix multiplication than convolution
- sparse matrix multiplication
 - is not as efficient as dense on parallel hardware
 - modern methods use coarse **partitioning** of nonzero elements
 - this is aligned with the Hebbian rule “**cells that fire together wire together**”

convolutional features are sparse

- deep layers have more features (e.g. 1024) and lower resolutions (e.g. 7×7)
 - detected patterns in many cases are as small as 5×5 , 3×3 or even 1×1
 - the convolution operation resembles more (sparse) matrix multiplication than convolution
- sparse matrix multiplication
 - is not as efficient as dense on parallel hardware
 - modern methods use coarse **partitioning** of nonzero elements
 - this is aligned with the Hebbian rule “**cells that fire together wire together**”

network in network (NiN)

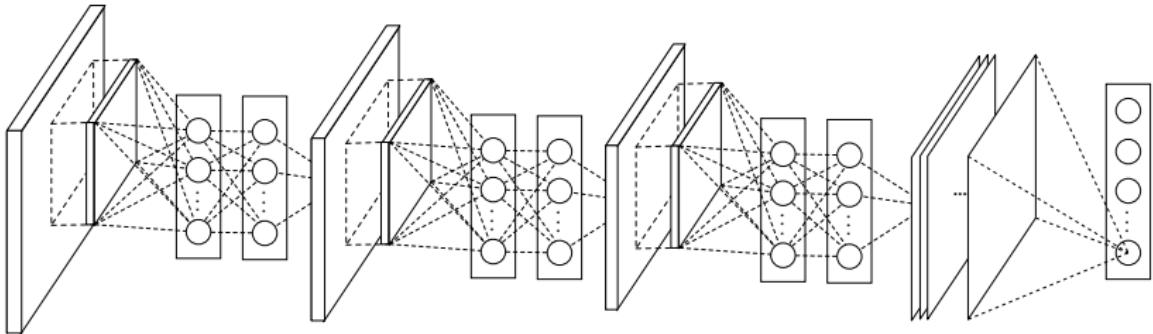

[Lin et al. 2013]

- activation functions are usually element-wise for simplicity; but here an entire **2-layer network** is used as activation function
- fully connected layers are simply replaced by **global average pooling**
- but this is nothing but convolution followed by two 1×1 convolutions
- 1×1 convolutions are just like matrix multiplications and can be used for **dimension reduction**

network in network (NiN)

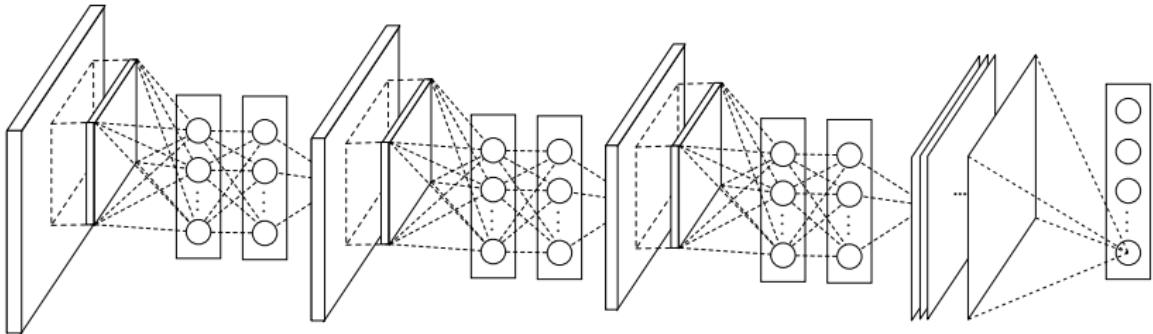

[Lin et al. 2013]

- activation functions are usually element-wise for simplicity; but here an entire **2-layer network** is used as activation function
- fully connected layers are simply replaced by **global average pooling**
- but this is nothing but convolution followed by two **1×1 convolutions**
- 1×1 convolutions are just like matrix multiplications and can be used for **dimension reduction**

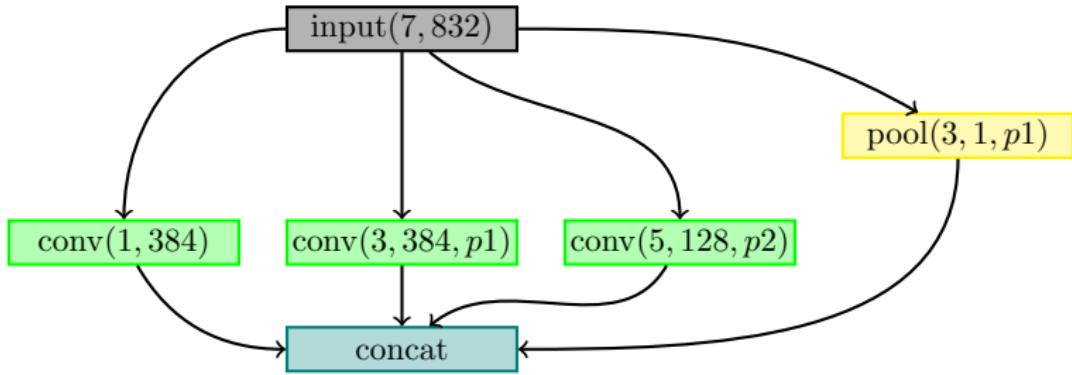

network in network (NiN)

[Lin et al. 2013]

- fully connected layers are simply replaced by **global average pooling**
- but this is nothing but convolution followed by two **1×1 convolutions**
- 1×1 convolutions are just like matrix multiplications and can be used for **dimension reduction**

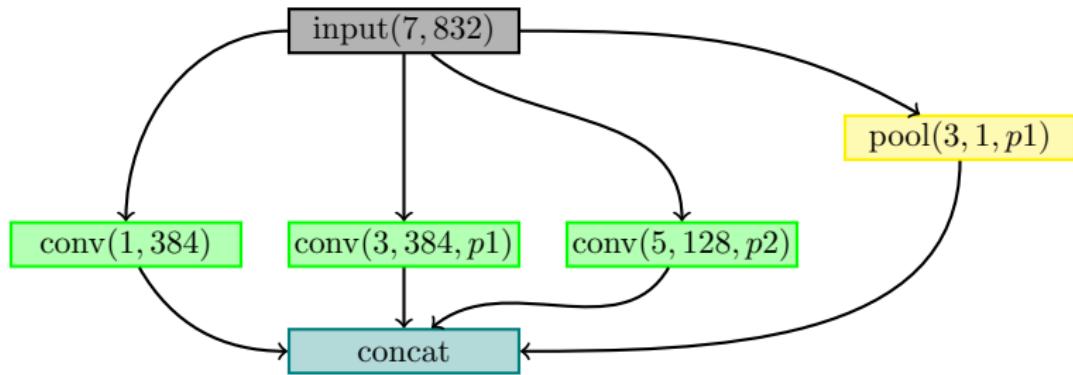

inception module

- **naive** inception module simply concatenates (feature-wise) three convolutions and one max-pooling
 - but this expensive and dimension keeps increasing
 - add **dimension reduction** to control cost, dimensions, and sparsity
 - this is referred to as **inception module**

inception module

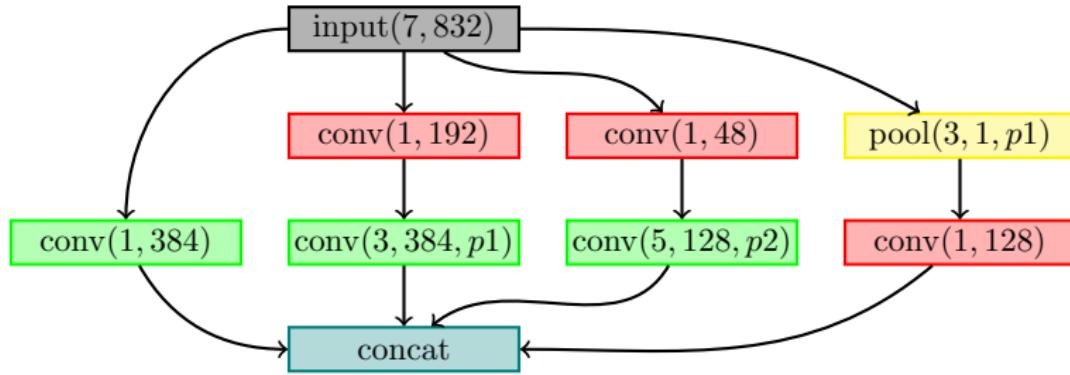

271,418,048 operations

- **naive** inception module simply concatenates (feature-wise) three convolutions and one max-pooling
- but this expensive and dimension keeps increasing
 - add **dimension reduction** to control cost, dimensions, and sparsity
 - this is referred to as **inception module**

inception module

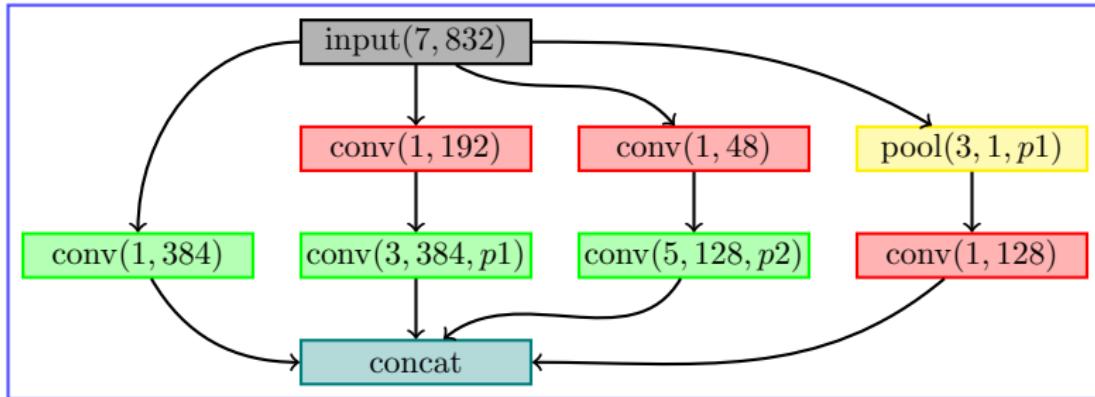

70,800,688 operations

- **naive** inception module simply concatenates (feature-wise) three convolutions and one max-pooling
- but this expensive and dimension keeps increasing
- add **dimension reduction** to control cost, dimensions, and sparsity
- this is referred to as **inception module**

inception module

70,800,688 operations

$\text{inc}(384, (192, 384), (48, 128), 128)$

- **naive** inception module simply concatenates (feature-wise) three convolutions and one max-pooling
- but this expensive and dimension keeps increasing
- add **dimension reduction** to control cost, dimensions, and sparsity
- this is referred to as **inception module**

alternatively: low-rank decomposition

$$Y = h \begin{pmatrix} W & X \end{pmatrix}$$

- X (Y): input (output) features (columns = spatial positions)
- W : weights; h : activation function
- low-rank approximation $W \approx UV^\top$; V is 1×1 spatially
- X was sparse; $V^\top X$ is not
- (in fact, V also includes a non-linearity)

alternatively: low-rank decomposition

$$Y \approx h \begin{pmatrix} U & V^\top & X \end{pmatrix}$$

- X (Y): input (output) features (columns = spatial positions)
- W : weights; h : activation function
- low-rank approximation $W \approx UV^\top$; V is 1×1 spatially
 - X was sparse; $V^\top X$ is not
 - (in fact, V also includes a non-linearity)
